## About the Office for National Statistics

The Office for National Statistics (ONS) is the Government Agency responsible for compiling, analysing and disseminating many of the United Kingdom's economic, social and demographic statistics, including the retail prices index, trade figures and labour market data, as well as the periodic census of the population and health statistics. It is also the agency that administers the statutory registration of births, marriages and deaths in England and Wales. The Director of ONS is also the National Statistician and the Registrar General for England and Wales.

## A National Statistics publication

National Statistics are produced to high professional standards set out in the National Statistics Code of Practice. They undergo regular quality assurance reviews to ensure that they meet customer needs. They are produced free from any political influence.

## About Health Statistics Quarterly and Population Trends

 Health Statistics Quarterly and Population Trends are journals of the Office for National Statistics. Each is published four times a year in February, May, August and November and March, June, September and December, respectively. In addition to bringing together articles on a wide range of population and health topics, Health Statistics Quarterly and Population Trends contain regular series of tables on a wide range of subjects for which ONS is responsible, including the most recently available statistics.
## Subscription

Annual subscription, including postage, is $£ 110$; single issues are $£ 30$. Subscriptions are available from Palgrave Macmillan, tel: 01256 357893 or www.palgrave.com/ons

## Online

Health Statistics Quarterly and Population Trends can be viewed or downloaded as Adobe Acrobat PDF files from the National Statistics website www.statistics.gov.uk/products/p6725.asp (Health Statistics Quarterly) or www.statistics.gov.uk/products/p6303.asp (Population Trends).

## Trends in life

## expectancy by social class, 1972-2005

The series on life expectancy by social class derived using the Office for National Statistics (ONS) Longitudinal Study has been updated on the National Statistics website to give data for the period 2002-05 for the first time. It is available at: www.statistics.gov.uk/statbase/Product. asp?vlnk=8460

The main points were:

- males in the professional class had a life expectancy at birth of 80.0 in the period 2002-05, compared with 72.7 years for those in the manual unskilled class
- females in the professional class had a life expectancy at birth of 85.1 years compared with 78.1 years for the unskilled manual class

Between 1972-76 and 2002-05, both males and females classified to non-manual occupations had a greater increase in life expectancy at birth and at age 65 than those classified to manual occupations.

In contrast, between 1997-2001 and 2002-05:

- life expectancy for males at birth and at age 65 increased more for those classified to manual occupations (1.8 and 1.2 years respectively), than to non-manual occupations ( 1.3 and 0.8 years respectively)
- for females, estimates of life expectancy increased by a similar amount for those classified to non-manual and manual occupations

> Healthy and disability-free life expectancy for local authorities in England and Wales, 2001

ONS has published estimates of healthy life expectancy (HLE) and disability-free life expectancy (DFLE) at birth and at age 65 for local authorities in England and Wales for the year 2001 on the Neighbourhood Statistics website, www. neighbourhood.statistics.gov.uk. Data are presented at national and Government Office Region (GOR) levels, in addition to local authority, and the data and meta data can be downloaded in a number of different formats. The healthy and disability-free life expectancy at birth and at age 65 figures are produced seperately for males and females.

The HLE estimates were calculated by combining:

- age and sex specific mortality rates (life tables), with
- age and sex specific rates of good/fairly good general health from the 2001 Census

The DFLE estimates were calculated by combining:

- age and sex specific mortality rates (life tables), with
- age and sex specific health rates of people reporting no limiting long-term illness, also from the 2001 Census

HLE and DFLE at birth and at age 65, calculated using the Sullivan method, are examples of summary measures of health known as health expectancies (such as expected years in good health or without a disability), which are commonly used for measuring and monitoring population health at national and international level. They are used as an indicator of progress in government strategies for tackling poverty and social inclusion, for sustainable development, and on public health. The provision of these estimates at local authority level extends their utility for use in local planning.

## Population estimates: mid-2006 and revised mid-2002 to mid-2005

## England and Wales/United Kingdom

On 23 August 2007 ONS published the mid-2006 population estimates and the revised mid-2002 to mid-2005 population estimates. These give estimates of the population for the United Kingdom; constituent countries; Government Office Regions; local authorities in England and Wales; Council Areas within Scotland; District Council Areas in Northern Ireland and Health Authorities/Boards. Full information on these mid-year population estimates are available on the National Statistics website at: www.statistics.gov.uk/popest

The revised 2002 to 2005 mid-year population estimates shown in this volume have been updated to include the latest revised estimates that take into account improved international migration estimates. Further details on the revisions are available at:
www.statistics.gov.uk/imps under 'Updates'.

## Scotland

Mid-2006 population estimates for Scotland were released by the General Register Office for Scotland on 27 July 2007. Information on these estimates are available at: www.gro-scotland. gov.uk/statistics/population.html

## Northern Ireland

Mid-2006 population estimates for Northern Ireland were released by the Northern Ireland Statistics and Research Agency on 31 July 2007. Information on these estimates are available at:
www.nisra.gov.uk/demography/default.asp? cmsid=20_21_24\&cms=demography_ population\%20statistics_Mid\%2Dyear+ population+estimates\&release=

## Consultation on restructuring ONS mortality statistics update

Following the recent consultation on mortality statistics, (which is available at: www.statistics. gov.uk/about/consultations/mortality_outputs. asp), ONS received ten responses from a variety of data users including the Department of Health, the Welsh Assembly Government and local authorities. Responses supported the proposal to change the reporting basis for mortality statistics from deaths occurring, to deaths registered, in a calendar year, as well as a move towards new themed packages of mortality outputs.

ONS intends to publish a report outlining the responses to the consultation before the end of the year on the National Statistics website. This will include more information on the future content of mortality outputs.

## Delay in publication of unexplained deaths in infancy report for 2006

The above report was due for publication in the autumn 2007 edition of Health Statistics Quarterly. The unexplained deaths report was first published in 2005 using 2004 data and we have since found that it is too early to publish provisional figures in the autumn as most of these deaths have not been registered by then.

The majority of the unexplained deaths are certified by a coroner either with or without an inquest and it takes much longer for these deaths to be registered. Hence the provisional figure for unexplained deaths is much lower when compared to the final figure. For example, provisional figures for 2004 showed there were 261 unexplained deaths and the rate was 0.41 per 1,000 live births while the final figures showed there were 309 deaths with a rate of 0.48 per 1,000 live births ( 17 per cent higher than the provisional rate). There was however a 12 month interval between the publication of these provisional and final figures. In order to publish meaningful, provisional figures for 2006, the number of unexplained deaths registered each month is currently being monitored. Figures will be published as soon as we are confident that most deaths have been registered.

## Effects of problems with birth and death registration systems on ONS statistical outputs

As described in the previous edition of Health Statistics Quarterly, problems with the introduction of the new registration on line system (RON) at register offices in England and Wales have led to the temporary suspension of some ONS outputs that rely on
the completeness of births and deaths registered between the end of March and the beginning of May 2007. Births and deaths records for this period, which were held only on paper at register offices, have now been entered onto the RON system. Statistical quality assurance and compilation processes are now being completed.

## How this affects reference tables in Health <br> Statistics Quarterly

Provisional conceptions figures for June quarter 2006 (which rely on March quarter 2007 and June quarter 2007 birth registrations), due to be published in the August edition of Health Statistics Quarterly, have been quality assured and are released in this edition. Provisional births, deaths and childhood mortality figures for the quarter ending March 2007 for England and Wales, also due to have been published in the August edition, are also included in this edition.

## Excess winter mortality

Unlike the winter edition of Health Statistics Quarterly in 2006, this edition does not contain a report on excess winter mortality. Provisional figures for winter 2006/07 have however been calculated and are available on the National Statistics website at:
www.statistics.gov.uk/statbase/Product. asp?vlnk $=10805 \&$ More $=\mathrm{n}$

These figures are available by age group, for England and Wales, English Government Office Regions, and Wales. Comparable trend data for winters from 1990/91 onwards are also available.

## Health at a Glance - OECD Indicators 2007

The Organisation for Economic Co-operation and Development (OECD) publishes a biennial summary of health and healthcare comparisons across its 30 member countries. Health at a Glance - OECD Indicators 2007 is due to be published during November and will be available at: www.oecd.org/health/ healthataglance. The content of Health at a Glance is based on the annual OECD health data collection, which ONS co-ordinates for the UK. OECD Health Data 2007: Statistics and Indicators for 30 Countries is available at: www.oecd.org/health/healthdata.
'Recent publications' are listed on page 96

# Social inequalities in adult male mortality by the National Statistics Socio-Economic Classification, England and Wales, 2001-03 

Chris White, Myer Glickman, Brian<br>Johnson and Tania Corbin<br>Office for National Statistics

This article reports social inequalities in mortality in men aged 25-64 years in England and Wales, in the period 2001-03 using unlinked data sources and 2001-04 using linked data sources. It represents the first official analysis of premature mortality by the final version of the National Statistics Socio-economic Classification introduced in 2001, and updates the tradition of decennial reporting of mortality by socio-economic status.

These results set a benchmark for inequalities in mortality in men of this age, providing insights into the impacts of different social and occupational circumstances in the early 21st Century and enabling future monitoring. The Office for National Statistics intends to extend this work to examine inequalities to mortality in females of the same age, in causes of death and by Government Office Region.

## Introduction

This article describes social inequalities in the all-cause mortality of men aged 25-64 years, in England and Wales, in the period 2001 to 2003. It is the first analysis of adult mortality using the final version of the National Statistics Socio-Economic Classification (NS-SEC), which was introduced in 2001; although previous analyses of male mortality for the period 1991-93 have been published, using an interim version of NS-SEC. ${ }^{1,2,3}$ This current analysis establishes an essential benchmark for the measurement of health inequalities in the early 21 st century, and it will inform the development of methods for future research, including options for an inter-censal time series. Further planned analyses of mortality by NS-SEC will report on females of working age, life expectancy, causes of death, and differences between Government Office Regions.

The analysis presented here uses four data sources: the 2001 Census, the mid-year population estimates for 2001-03, deaths of men aged 25-64 occurring in 2001-03, and the Office for National Statistics (ONS) Longitudinal Study (LS). The LS is a sample of around one per cent of the population of England and Wales, which links census and vital events data from 1971 onwards. ${ }^{4}$ This analysis departs from previous decennial analyses of mortality by socio-economic status through explicit use of linked records from the LS to quantify and correct for the potential for previously reported biases in unlinked data, ${ }^{5,6}$ allowing a more valid and reliable set of estimates with which to establish trends in the future.

## Background

Social inequalities in mortality in the UK are well-established, particularly among men of working age, and their study has a history
dating back to the Registrar General's reports of the mid-nineteenth century. ${ }^{7,8,9,10,11,12}$ The large body of evidence assembled since the publication of the influential Black Report in 1980 shows that such inequalities are a feature of many industrialised societies, ${ }^{13,14,15}$ and that a gradient in mortality risk can generally be observed across the range of socio-economic groups in society, however those groups are categorised. ${ }^{16,17}$

Since 1911, the principal social classification used in UK official statistics has been the Registrar General's Social Classification (RGSC) based on occupation and employment status. Significant inequalities in mortality by RGSC have been reported in the literature throughout the 20th century. While mortality rates overall declined during the 20th century, the gap in mortality across the social spectrum has persisted or widened. ${ }^{9,18,19}$ In 1931, the mortality rate among unskilled male workers was 1.2 times the rate among professionals; this difference had increased to 2.9 times in 1991-93..$^{20,21}$ The marked contrast between professionals and unskilled manual workers in the rate at which mortality fell between 1970-72 and 1991-93 was responsible for the widening of the social class gradient among men of working age during this period. The scale of inequality in mortality can be illustrated with reference to age-specific rates of death: in 1991-93, men in unskilled occupations aged 20-24 had a higher rate of death than professional men aged 40-44. ${ }^{21}$ This increasing inequality in mortality risk by socio-economic status led the UK government to commission a second independent inquiry into inequalities in health ${ }^{22}$ in 1997, which led to the funding of a number of national initiatives designed to tackle the poorer life chances of the socially disadvantaged. ${ }^{23,24,25}$

The RGSC has provided a relatively consistent basis for the monitoring of health inequalities over time, but has been criticised for lacking a coherent theoretical basis and insensitivity to the changing patterns of industry and employment in modern economies. ${ }^{26}$ The diminishing number of men in unskilled manual occupations (social class V) since 1970 has led to criticism of RGSC from both statistical ${ }^{27,28}$ and sociological perspectives; ${ }^{29,30}$ the health status of this social group can be seen as of decreasing relevance to the population as a whole, ${ }^{31}$ and increasingly difficult to measure with statistical reliability. At the same time, the expansion of managerial, technical and routine non-manual occupations during the 1980s and 1990s reflects the impact of a growing service-based economy, and casts increasing doubt on the hierarchical social distinctions implicit in the RGSC. ${ }^{32}$

The NS-SEC, like the RGSC, is based on occupation and employment status (and for some occupations, number of employees in the workplace) but was developed on the basis of a classification of employment relations, and aims to reflect the socio-economic structure of 21 st century societies and the major shift in the UK economy from manufacturing to service industries. ${ }^{33}$ Important distinguishing features include the separation of small employers and own-account workers into a discrete class, the removal of the historical distinction between manual occupations and other occupations of a routine or semi-routine nature and an increase in the size of the class populations at the extremes of the scale. Another difference between the classifications is that RGSC is an assumed hierarchy of occupational skill and social standing, whereas NS-SEC is an explicit measure of employment relations characteristics ${ }^{34}$ that aims to minimise within-class and maximise between-class heterogeneity. ${ }^{33}$ The capture of qualitative differences in employment relations inherent in the NS-SEC schema counters the assumption of a hierarchy of classes, but establishes distinct occupational groupings, which provide greater scope for explaining statistical relationships. Specifically, the relationship between mortality and NS-SEC can suggest how different types of employment relations and conditions may impact on health, and, consequently, the role of social organisation in the formation and persistence of health inequalities.

Previous analysis of mortality in males of working age by an interim version of NS-SEC examined deaths in the period 1991-93 by major cause. For all causes of death, although statistically significant differences were found between classes, the mortality pattern departed from the familiar linear relationship characteristic of analyses by social class in one important respect; the Small employers, own account workers had lower mortality than men working in Intermediate and Lower supervisory and technical occupations. ${ }^{2}$ Another relevant distinction between analyses by RGSC and NS-SEC in the period 1991-93 was the lower rate of death found among men working as Large employers, higher managers compared with men in RGSC social class I, and the lower rate in men working in Routine occupations compared with men in RGSC social class V. The lower mortality rate at each end of the NS-SEC scale maintained consistency with the gradient found in analysis by RGSC for the same period.

Further information about NS-SEC, its rationale, development, and application is available on the National Statistics website. ${ }^{35}$

## Analytical approach

Examinations of social inequalities in mortality have generally used one of two approaches, the cross-sectional approach using unlinked records, or the follow-up approach, using linked records. The decennial analyses published by ONS and its predecessors have used unlinked records, in which mortality rates are calculated using the population recorded at a census as the denominator and the number of deaths registered in a period around the census as the numerator. Since the inception of the LS, many important analyses have used the linked records approach, which tracks a defined sample of individuals over time. ${ }^{6,7,11, ~ 12, ~ 17,21,36,39, ~}$ ${ }^{56,66}$ Mortality rates calculated from linked records use the time members accrue in the sample (person years at risk, PYRs) as the denominator and deaths to sample members as the numerator.

Both approaches have strengths and weaknesses. The unlinked approach is subject to numerator-denominator biases, in particular, but, as the figures are based on the entire population, the data allow analyses into detailed breakdowns and the results have a high level of stability. Numerator-denominator biases can arise from differences in the reporting of occupation and employment status, and hence NS-SEC, at death registration and census. ${ }^{5,36,37}$ One difference is that reporting at census is generally by the individual concerned, whereas at death it is by the person registering the death, and may therefore be less accurate. Another is that the information provided at census relates to current or most recent occupation and economic position, while at death what is recorded is usually the main lifetime occupation or career.

The potential for numerator-denominator biases is particularly relevant for analyses using the 2001 Census; a rule applied by ONS in the processing of records coded men and women under the age of 65 reporting an occupation to the residual NS-SEC category Not classifiable for other reasons if they had not worked since 1995 and were not classified as 'never worked' or 'long-term unemployed'. ${ }^{38}$ This rule (known as Filter X) has the potential to distort mortality estimates by socio-economic status through the artificial reduction of occupied NSSEC populations at census and differential occupational propensities for not having worked since 1995. This coding rule was not applied to 2001 Census records in the LS, enabling the use of linked records to correct for numerator-denominator biases resulting from Filter X, described below.

Another weakness of analyses using unlinked records is the inability to detect and account for the possible presence of health selection, which also has potential to distort inequalities in mortality by socioeconomic status. The operation of health selection is complex, and has received substantial examination in the literature. ${ }^{7,15,21,39,40,41,42,66}$ The
principal tenet of the selection explanation for inequalities in mortality by socio-economic status relevant to this analysis is the direction of the relationship between health and social position: that is, that health status influences social position rather than vice versa, leading to a concentration of people at higher risk of premature death in low status occupations or unemployed or permanently sick or disabled. If the propensity for an individual to retire early or leave the labour market on grounds of ill-health varies between occupations, this is likely to affect the comparison of mortality rates by NS-SEC, since such individuals are at increased risk of subsequent death. The linked records approach using data from the LS can adjust for health selection out of the labour market by allocating an occupied NS-SEC from the LS member's 1991 Census record if available.

While the linked records contained within the LS provide a number of methodological advantages described above, estimates of mortality based on the LS alone are subject to sampling variation, which limits the scope for detailed analysis by socio-economic status and cause of death. Furthermore, the potential for underestimation of loss to follow-up brought about by an unknown rate of unobserved embarkation can result in sample members continuing to accrue person years at risk when they are no longer resident in England and Wales, thereby reducing estimates of mortality.

To provide the most reliable comparison of mortality by NS-SEC for adult males, this article draws on both unlinked and linked records, explained in the Methods section below. Mortality rates are calculated using a combination of both approaches, including adjustments applied in each set of calculations to compensate for known biases specific to the data sources. In particular, the analysis draws on linked records in two ways to improve the unlinked records analysis.

Firstly, it takes advantage of the fact that the LS is a representative sample; this means that results calculated from the LS should be broadly similar to those calculated from unlinked records, subject to sampling error and known differences in method of NS-SEC assignment. ${ }^{1}$ Significant differences between the two sets of results are therefore suggestive of systematic bias in one or the other and can be investigated to improve the overall robustness of the findings. Secondly, the LS contains data on the same individuals collected at successive censuses and at death registration. This means that the relationships between (for example) the NS-SEC class allocated at the 2001 Census and that allocated to the same person at death can be compared and used to refine the methods for unlinked analysis.

Details of the adjustments made and the calculations at each intermediate stage in the process will be provided in a subsequent technical paper. Some additional tables and background material have been provided in a separate Appendix to this article; tables and boxes referred to below by an alphanumeric character (for example, Box A1) can be found in the Appendix.

## Methods

## National Statistics Socio-Economic Classification (NS-SEC)

Box One shows the analysis according to the nine class breakdown of NS-SEC and provides examples of the occupations included in each class. These analytical classes are based on a larger number of operational categories (and sub-categories) and can be further aggregated into broader divisions ( 5 and 3 analytic class versions), shown in Box A3 in the Appendix.

There are three principal methods of deriving NS-SEC, depending on the data available. ${ }^{43}$ The full method requires occupational information

## Box one

## National Statistics Socio-Economic Classification Analytic classes

|  | alytic class | Examples of occupations included |
| :---: | :---: | :---: |
|  | Large employers, higher managers | Senior officials in national and local government, directors and chief executives of major organisations, officers in the armed forces |
|  | Higher professionals | Civil engineers, medical practitioners, physicists, geologists, IT strategy and planning professionals, legal professionals, architects |
| 2 | Lower managerial, professional | Teachers in primary and secondary schools, quantity surveyors, public service administrative professionals, social workers, nurses, IT technicians |
| 3 | Intermediate | NCOs and other ranks in the Armed Forces, graphic designers, medical and dental technicians, Civil Service administrative officers and local government clerical officers, counter clerks, school and company secretaries |
| 4 | Small employers and own account workers | Hairdressing and beauty salon proprietors, shopkeepers, dispensing opticians in private practice, farmers, self-employed taxi drivers |
| 5 | Lower supervisory and technical occupations | Bakers and flour confectioners, screen-printers, plumbers, electricians and motor mechanics employed by others, gardeners, rail transport operatives |
| 6 | Semi-routine occupations | Pest control officers, clothing cutters, traffic wardens, scaffolders, assemblers of vehicles, farm workers, veterinary nurses and assistants, shelf fillers |
| 7 | Routine occupations | Hairdressing employees, floral arrangers, roundsmen and women, sewing machinists, van, bus and coach drivers, labourers, hotel porters, bar staff, cleaners and domestics, road sweepers, car park attendants |
|  | Never Worked, long-term unemployed | Defined at census as a person aged 16-74 who had never engaged in paid employment or had not worked since 1999 |
| Source: NS-SEC User Manual |  |  |

coded to the Standard Occupational Classification 2000 (SOC 2000), details of employment status (for example supervisor, other employee, or self-employed) and the size of the organisation for which the individual works. The reduced method dispenses with organisational size and derives NS-SEC from the SOC 2000 code and employment status, while the simplified method derives NS-SEC from the SOC 2000 code only.

A study using the Labour Force Survey in 2000 found that compared with the full method, the reduced method allocated 98 per cent of individuals to the correct NS-SEC analytic class. ${ }^{33}$ The main effect of using the reduced method was to increase the proportion of the study population working as Large employers, higher managers from 4.4 per cent to 5.9 per cent, and reduce the proportion working in Lower managerial, professional occupations from 25.0 per cent to 23.3 per cent. A comparison of the allocations to the NS-SEC analytic classes using the full and reduced methods of derivation, based on that study, is shown in Table A1 in the Appendix.

Full NS-SEC can be derived from the 2001 Census data, but not from death registrations, because size of organisation is not among the occupational details recorded on the death certificate. For consistency, therefore, reduced NS-SEC was used throughout this analysis. The census questions on occupation and employment status are shown in Box A1 and the rules for recording of the relevant information at death registration are set out in Box A2.

During the development of the NS-SEC, a version for use with data coded to the Standard Occupational Classification 1990 (SOC 90) was made available (referred to as NS-SEC90). ${ }^{44}$ Although the categories and analytic classes of NS-SEC90 are identical to those of NS-SEC,
differences between the SOC 90 and SOC 2000 classifications mean that the two are not directly equivalent. A previous analysis of deaths registered in 2001, which were coded using both SOC 90 and SOC 2000, found that allocation to NS-SEC and NS-SEC90 classes agreed in 90 per cent of cases overall. ${ }^{45}$

## Analysis period and study populations

Death registrations record information on the occupation and employment status of the deceased for men between the ages of 16 and 74. However, the completeness of these data deteriorates after the state retirement age of 65 , reducing the reliability of analysis by NS-SEC from this source beyond the age of 64 . The trend for an increasing proportion of young men to delay entry into the labour market, usually because of their continuation in full-time education beyond the age of 16 , also reduces the proportion of men aged 16-24 who can be allocated an NSSEC class based on their occupation. Consequently, this analysis focuses on men aged 25-64, to ensure the most complete and reliable allocation to NS-SEC classes.

## Deriving population denominators by NS-SEC

Mid-year population estimates 2001-03 by NS-SEC
It is customary for a decennial analysis of mortality to focus on deaths in a period evenly spread before and after the census year. However, the introduction of NS-SEC for death registrations from January 2001 makes that impossible in this case. Consequently, deaths of men resident in England and Wales registered in the calendar years 2001 to 2003 were used. Because this means that the census-based population counts are not centrally positioned in the analysis period, and to allow for revisions to the 2001 Census populations which have subsequently been published by ONS, adjusted denominators were derived for use in the decennial analysis of unlinked records by applying the proportions of the male population in each NS-SEC class and five-year age group to the ONS revised mid-year population estimates for each of the three years. The adjusted total population denominator was 41,507,100 PYRs for 2001-03 combined, representing an increase of 1.7 per cent in the denominator compared to the census counts. Population numbers (rounded to thousands) by age group and NS-SEC class from the 2001 Census are shown in Table A2 in the Appendix, and the equivalent numbers using ONS mid-year population estimates are shown in Table A3.

## Using linked data to refine population estimates

The analysis of linked records concentrated on male members of the LS, included if they were enumerated in England and Wales at the 2001

Census, were aged 25-64 years on the census date, and were traced at NHS Central Register (this ensures the inclusion of death records where appropriate). A total of 139,760 LS members were included in this sample. Person years at risk were calculated for the period 29 April 2001 (census day) to 31 December 2004, taking account of emigrations from and re-entries to England and Wales and ageing-out of the population at risk. These linked records were used to (a) reduce the proportion classified to the residual category Not classifiable for other reasons (artificially inflated by the application of the Filter X rule in the 2001 Census), (b) minimise the potential for health selection out of the labour market to disproportionately diminish occupied NS-SEC analytic class denominators. The age and NS-SEC class-specific proportions of PYRs were applied to the pooled mid-year population estimates for England and Wales for the years 2001-03 to produce synthetic unlinked records denominators optimised for mortality analysis. The rounded denominators by NS-SEC class and age group are presented in Table 1. The unrounded version of this table will be available on the National Statistics website.

The Longitudinal Study sample members were allocated to an NS-SEC class based on their 2001 Census record. To maximise the number of individuals available for analysis and to reduce the possible effect of health selection out of the labour market, those who had no occupied NS-SEC class in 2001, but were present and had an occupation coded to SOC90 at the 1991 Census, were then allocated to an NS-SEC class on the basis of their NS-SEC90 code. In linked records 95.9 per cent of the LS sample was allocated to an occupied NS-SEC class using NS-SEC in 2001 only, and 97.9 per cent using NS-SEC90 in addition. The PYRs providing the denominators for the linked records analysis are shown (by NS-SEC class, all ages combined) in Table 2.

## Adjustments to the assignment of deaths (numerator) to NS-SEC

A total of 150,201 deaths were included in the unlinked records analysis; 89.3 per cent of these could be allocated to an occupied NS-SEC class. Preliminary investigation of linked records using the LS revealed a systematic bias in the unlinked records analysis caused by an apparent misallocation of one NS-SEC operational category at death registration. Certain occupations are assigned to NS-SEC operational category L6 (Higher Supervisory occupations), which is part of the analytic class Lower professional, managerial, if they supervise other employees and have an employment status of supervisor, and operational category L7 (Intermediate occupations), which is part of the Intermediate

analytic class, if not; however their job titles typically make no mention of management or supervisory responsibilities in either case. Examples include draughtsmen, various categories of clerical workers, photographers, and electrical technicians. For those men assigned to NSSEC operational category L6 at census and L7 at death in the LS sample, equivalence was found in the occupation reported in their linked census and death record, and differed only in regard to the employment status reported. While this issue has no effect on the linked records analysis, which is based on NS-SEC allocated at census for both deaths and PYRs, it distorts the mortality rates produced from unlinked records for these analytic classes. The rule for coding employment status, a fundamental factor in the decision to allocate to either L6 or L7, in death registrations, when employment status information is missing or insufficiently detailed, is to default to the employee category. This rule increases the likelihood
for deaths in these occupations to be classified to the operational category Intermediate occupations (L7) and hence the Intermediate analytic class.

To adjust for this bias, while ensuring that the total number of deaths remains consistent, age-specific adjustment factors were calculated from the LS sample and applied to the numbers of deaths in the Lower professional, managerial and Intermediate analytic classes in the deaths registrations data. The resulting per cent change in deaths in each class and the adjustment factors are shown in Table A4 in the Appendix. This reduced the number of deaths allocated to the Intermediate analytic class by 23 per cent and increased the number of deaths allocated to the Lower managerial, professional analytic class by 9 per cent in death registration records.

The information collected at death registration does not allow reliable identification of men who had Never worked or were Long-term unemployed, or differentiation between those categories and men who could not be allocated to an NS-SEC class due to inadequate information or for other reasons. Full-time students are identified, but deaths in this group are uncommon. Consequently, mortality rates based on the unlinked records approach are presented for occupied NS-SEC analytic classes only.

A total of 1,678 deaths occurring between census day 29 April 2001 and 31 December 2004 were included in the analysis of linked records using the LS. The NS-SEC distribution of deaths found in the LS sample enumerated in 2001 takes account of potential health selection bias by allocating the sample member's NS-SEC90 class from their 1991 Census record, if available, to assign NS-SEC in 2001. Linked records include the reliable capture of the NS-SEC operational category Never worked, long-term unemployed, enabling the calculation of mortality estimates for this group, in addition to occupied NS-SEC analytic classes.

## Outcome measures

To compare the mortality experience of NS-SEC analytic classes, two measures of mortality were calculated: firstly, age-specific mortality rates for five-year age groups and secondly, directly age-standardised mortality rates for all men aged 25-64 standardised to the European standard population (see Table A5). Age-standardised rates are a summary measure allowing populations with differing age structures to be reliably compared.

## Results

## Distribution of deaths by NS-SEC and data source

Table 3 shows the number and per cent of deaths by NS-SEC class, by data source and method of assignment. The class distribution of deaths from death registrations takes account of the application of age-specific adjustment factors to the NS-SEC analytic classes Lower managerial, professional and Intermediate, explained earlier. The largest number of deaths was allocated to men working in Routine occupations, who made up 21.5 per cent of all deaths in the unlinked data and 21.6 per cent in the LS sample after adjustment for health selection.

The unlinked and linked records differed noticeably in the proportions of deaths assigned to the Lower managerial, professional and
Intermediate analytic classes before the adjustment for misallocation described earlier. Specifically, the Intermediate analytic class had a statistically significant lower proportion of deaths and the Lower managerial, professional analytic class a significantly higher proportion in linked records compared with death registrations. This significant difference disappeared following adjustment for misallocation of certain occupations in death registrations.

The proportion of deaths allocated to the Large employers, higher managers analytic class was significantly higher in the LS at 5.1 per cent after adjustment for health selection, compared with 3.5 per cent of death registrations, but in other occupied classes differences were within the range of sampling variation.

Table 4 compares the NS-SEC assignment at census and death registration of the members of the LS sample who died in the study period. Overall, 53.3 per cent of those in occupied NS-SEC analytic classes were allocated to the same class at death as was reported in the census (range 40.7 per cent in the Large employers, higher managers analytic class to 65.0 per cent in the Routine analytic class), while 20.0 per cent were reported at death in a more advantaged class than at census, and 26.7 per cent in a less advantaged class.

The discrepancy in designation to NS-SEC Large employers, higher managers analytic class at census and death registration is apparent in Table 4. Only two-fifths of deaths assigned to the Large employers, higher managers analytic class at census were also assigned at death registration, with the majority not assigned, allocated to the Lower managerial, professional analytic class. A similar, although smaller,
discrepancy was found in assignment to Large employers, higher managers at death registration compared with assignment at census.
The greater likelihood for Large employers, higher managers to be allocated to the Lower managerial, professional analytic class at death registration partly explains the higher proportion of deaths found in assignment to Large employers, higher managers in linked records compared with unlinked death registrations.

The inadequacy of allocations to the NS-SEC operational category Never worked, long-term unemployed at death registration is verified in the examination of linked records. While more than 70 deaths were allocated to this NS-SEC operational category on LS members' census records, fewer than five were allocated at death registration. This finding shows that valid estimates of mortality for the Never worked, long-term unemployed cannot be calculated from the unlinked records.

## Age-specific mortality rates by NS-SEC

Age-specific mortality rates by NS-SEC, calculated using the unlinked records approach, are presented in Table 5. The well-established increase in risk of death with increasing age is illustrated for each class separately in Figure 1. The class-specific relative increase with age is greatest in the Higher professional analytic class with a 33 -fold increase in rate of death in 60-64 year olds compared to ages 25-29, while the men working as Small employers, own account workers had only an 11 -fold increase between these ages. The inequality in relative risk of death between men working in Routine occupations and men working as Large employers, higher managers falls with increasing age. At ages 25-29, men in Routine occupations are more than four times more likely to die than men working as Large employers, higher managers, while at ages 60-64 the disparity in the rate of death falls to two and a quarter times greater. The contrast in mortality is further emphasised when comparing the mortality rate of the Routine analytic class at ages 25-29 with the mortality rate among men working as Large employers, higher managers fifteen years their senior. At ages 40-44 and 45-49, Large employers, higher managers have a lower rate than men working in Routine occupations fifteen years their junior.

The relative ranking of analytic classes in the mortality of men at the youngest ages (see Figure 2), shows men working as Small employers, own account workers had a raised rate of death compared with men working in Lower supervisory and technical occupations at ages 25-29, and a similar rate to men working in Semi-routine occupations. The Lower supervisory and technical analytic class experience lower

mortality than Small employers, own account workers at ages 30-39, but this pattern reverses at ages 45-64 (see Figure 3), demonstrating that the lower age-standardised rate of death to men working as Small employers, own account workers compared with men in the Lower supervisory and technical analytic class is predominantly a function of their lower mortality risk at older ages.

## Age-standardised mortality rates by NS-SEC and data source

Table 6 presents age-standardised mortality rates per 100,000 PYRs, with 95 per cent confidence intervals, by NS-SEC using the unlinked and linked approaches.

In the analysis of unlinked records, the mortality rate of men working in Routine occupations was 513 per 100,000 PYRs, nearly three times the rate of 182 per 100,000 in men working as Large employers, higher managers. Mortality rates differed significantly between each NSSEC analytic class, with the gap between NS-SEC-specific rates most pronounced between men working as Small employers, own account workers and men working in Lower supervisory and technical occupations, and between men in Lower supervisory and technical occupations and Semi-routine occupations.

In the linked records analysis, age-standardised mortality rates were lower than or the same as the unlinked records rates in all analytic classes except the Large employers, higher managers analytic class (see Figure 4). However, only the difference for the Routine analytic class lay outside the 95 per cent confidence interval. A weaker gradient between Large employers, higher managers and men working in Routine occupations is found for the linked compared to the unlinked analysis, partly as a result of a higher rate of death in the Large employers, higher managers and partly due to a lower rate in the Routine analytic class.

The three NS-SEC analytic classes with a predominant service relationship form of employment regulation (that is, analytic classes 1.1, 1.2 and 2) have statistically significant lower rates of death compared with the three classes regulated by a labour contract (that is, classes 5, 6 and 7).

Men in the LS sample classified as Never worked, long-term unemployed had a rate of death of 989 per 100,000 PYRs, four and a half times higher than that of men working as Large employers, higher

managers, and two and a quarter times higher than men working in
Routine occupations.

For comparison, the rates of death from the unlinked records analysis with and without the adjustment to operational categories L6-Higher supervisory occupations and L7-Intermediate occupations described earlier are shown in Figure A1 in the Appendix.

## Mortality in condensed versions of NS-SEC

Table 7 presents age-standardised mortality rates per 100,000 PYRs, with 95 per cent confidence intervals, by NS-SEC analytic five class breakdown using the unlinked records method. The rate of death among men in the Semi-routine and Routine class is 2.2 times greater than that observed among men in the Managerial and Professional class, and a progressive, statistically significant pattern of increasing mortality with more disadvantaged socio-economic status is discernable between the intervening adjacent classes.

The corresponding mortality rates for the three class NS-SEC scale are presented in Table 8. The rate of death in men working in Routine and Manual occupations is twice as high as that in the Managerial and Professional analytic class, demonstrating the capability of the NS-SEC to discriminate mortality risk in its most condensed form.

## Comparison with previous time periods

While direct comparison with earlier decennial analyses is difficult because of the change in socio-economic classifications, an indication of the scale of social inequalities over a thirty year period is presented in Table 9, based on a comparison of rates for the extremes of the RGSC and NS-SEC. Rates of death among men working in the most advantaged occupational group have fallen by more than 60 per cent since 1970-72, compared with only 40 per cent for those in the least advantaged group.

Comparison of age-standardised mortality rates in men aged 20-64 by RGSC for 1970-72, 1979-83 and 1991-93 and men aged 25-64 by NS-SEC for 2001-03

Source: Health Inequalities Decennial Supplement, Series DS No. 15, TSO: London for RGSC; death registrations for 2001-03 and optimised population estimates (see Methods)

The lower rate of death found in men working as Large employers, higher managers in 2001-03 compared with men working as professionals in 1991-93 is of a similar order of magnitude to the lower rate of death in men working in Routine occupations compared with men working in unskilled manual occupations. Consequently, the gradient in mortality persists despite the lower rates of death reported for NS-SEC analytic classes 1.1 and 7 compared with RGSC I and V.

## Discussion

The age-standardised mortality rates by NS-SEC, calculated from death registrations and optimised class denominators and reported in Table 6, set a benchmark against which future analyses of mortality in men of working age can be compared. These rates represent the most valid and
reliable estimates achievable from the design limitations imposed by the use of unlinked data sources. The concurrent use of the LS in this decennial analysis has shown its value by uncovering the presence of occupational data weaknesses in unlinked deaths and population records, which are capable of producing distortions in mortality estimates by NS-SEC.

This analysis shows a clear social gradient in mortality for men of working age in the early years of the 21 st century. Although NS-SEC was not designed as a hierarchy of occupations, ${ }^{33}$ each analytic class has a distinct and (in the unlinked records analysis) significantly different agestandardised all-cause mortality rate, showing a clear gradient from low mortality among men working as Large employers, higher managers or as Higher professionals through to high mortality in men working in Routine occupations. This suggests that the NS-SEC, which is based on employment relations, discriminates well between social groups with differing opportunities and experiences. The overall pattern between classes and the magnitude of the difference in mortality risk between the most advantaged and least advantaged occupational groups is similar to that found in previous analyses using RGSC. ${ }^{3,7,9}$ The broad equivalence of most of the NS-SEC analytic classes to the RGSC classes occupying similar positions in the scale is apparent.

Even within the larger confidence intervals in the analysis using linked records, NS-SEC classes encompassing large employers, managers and professionals showed significantly lower mortality rates than the Lower supervisory and technical, Semi-routine and Routine analytic classes. The former three analytic classes are characterised by a service relationship and the latter three by a labour contract relationship, with the Intermediate and Small employers, own account workers having an intermediate employment relations position. ${ }^{33}$ The division into Professional and Managerial, Intermediate and Routine and Manual classes in the most condensed version of the NS-SEC analytic classification ${ }^{35}$ is thus a potentially useful one for the summary description of inequalities in mortality, while recognising that this will conceal important differences within the broader groupings.

The gradients in mortality by RGSC have been explained in the literature in terms of a clustering of attributes of advantage among professionals and disadvantage among unskilled manual workers, ${ }^{46}$ and their accumulation and intensity over the life course. ${ }^{47}$ Circumstances of disadvantage such as poor quality housing, exposure to environmental pollution in area of residence, occupational hazards, poor diet, smoking, risk of unemployment, and low income ${ }^{48}$ were found to be finely graded between the social classes, most concentrated in social class V with diminishing levels of exposure for each step up the social hierarchy. The presence of a gradation of mortality risk across the hierarchy rather than coherence in mortality risk beyond a specific threshold has been used to justify the relevance of the materialist explanation for inequalities in health. ${ }^{37}$ The mortality pattern by NS-SEC is also graded and may indicate a similar analytic class relationship to these domains of material disadvantage.

Explanations for inequalities in mortality related to employment relations concepts inherent to the NS-SEC such as work control and job strain (high demands in the presence of low control) have been addressed in previous research. The Whitehall II study showed an association between low job control, low employment grade and future development of heart disease, ${ }^{49}$ while other studies have demonstrated a connection between high job strain and hypertension. ${ }^{50,51}$ In addition to job strain, psychosocial work hazards such as effort-reward imbalance ${ }^{52}$ (high effort and low rewards in terms of pay, security, recognition and career progression opportunities) and its influence on cardiovascular health has been investigated. The link between high blood pressure, harmful levels of blood lipids, and future development of cardiovascular disease was found in people experiencing effort-reward imbalance. ${ }^{53,54,55}$ Further analyses reporting mortality patterns by NS-SEC in major causes of death will
provide more relevant evidence of the impact of employment relations on premature mortality from specific causes of death. Generally, the literature suggests that occupations with greater autonomy and control experience better health, ${ }^{3,56}$ and the differences in mortality rates reported here support this conclusion.

The higher rate of premature death found among the Never worked, long-term unemployed compared to all men aged 25-64 in 2001 in the Longitudinal Study is consistent with previous analyses and demonstrates the persistent mortality disadvantage associated with this economic position. ${ }^{7,9,17,57,58,59,60,61}$ Men of working age found to be seeking work at both the 1971 and 1981 censuses had rates of death twice the average for England and Wales during the period 1981-92, while the current analysis reports a three-fold raised rate compared to all men aged 25-64 enumerated in 2001. The larger excess mortality found may be partly explained by the different definitions of unemployed in the censuses of 1971 and 1981 and at 2001. The latter indicates a period of unemployment lasting more than a year and encompasses the never worked, whereas the former is defined by an economic position of seeking work in the past week. The 2001 Census definition of long-term unemployed, used in the NS-SEC schema, represents a more marginalised population with apparent difficulty in securing a place in the labour market.

Previous research has challenged the confounding influence of preexisting ill-health,,${ }^{32,57,59}$ educational attainment, ${ }^{60}$ housing tenure, ${ }^{17}$ occupational class, ${ }^{17,57}$ or health-damaging behaviour ${ }^{61}$ as adequate explanations for the higher rate of mortality found among those exposed to unemployment, suggesting a distinct, independent influence. The importance of unemployment for future mortality risk necessitates regular monitoring. We emphasise that mortality rates for the Never worked, long-term unemployed can only be reliably estimated using the linked records approach. The contrast between proportions of deaths classified to the Never worked, long-term unemployed at census and at death registration is marked, confirming death registrations do not capture the true population of unemployed individuals.

The age-specific mortality rates reported show that, with some exceptions, the patterns of mortality by NS-SEC class are consistent throughout the age range examined. Relative differences between classes are greater at younger ages, while absolute differences are greater at older ages. The pattern of age-specific rates among Small employers, own-account workers is unusual. Men in this analytic class had higher mortality than men in the Lower supervisory and technical analytic class at ages 25-34, but lower mortality than the Intermediate analytic class at ages 50-54. These findings merit further investigation, and the reasons may become clearer when the data are analysed by cause of death.

## Differences between linked and unlinked results

Although the pattern of age-standardised mortality rates by NS-SEC is broadly similar whether the unlinked or linked record approach is used, there are three main differences, which are distinct but connected. The first difference relates to source of assignment of NS-SEC. The linked records approach allocates deaths to the NS-SEC class from the 2001 Census record, while the unlinked records approach allocates deaths from the death registrations records. The large discrepancy found between the death registrations and the LS sample in allocation to the 'inadequately described' suggests that the occupational information elicited at census is substantially more detailed and complete than that recorded at death registration. This is likely to reflect both the specific questions and coding rules, and the fact that reporting at death relies on the knowledge the informant has about the deceased.

A second difference between the census and death registrations in the designation of NS-SEC is particularly relevant for the capture of the Long-term unemployed. The 2001 Census defines the NS-SEC
category of Long-term unemployed as having not worked since 1999 and seeking work, enabling derivation of this class from the last year worked indicator and economic activity. Consequently, the probability of recording completely and accurately this NS-SEC class is greater at census than at death registration. Death registration data for the period 2001-03 indicate some ( 0.4 per cent) men were designated to an NS-SEC of Long-term unemployed, but the rules for recording of occupation at death registration state the last gainful occupation should take precedence for persons currently unemployed (see Box A2).

## The influence of differential capture of the Long-term unemployed

 on the resultant occupied class gradient in each approach may function through disproportionate risk of exposure to unemployment in some social groups more than others in the study period. A key component of employment relations, entrenched in the NS-SEC, is security of employment, with greater security in occupations regulated by a service relationship and less security in occupations regulated by a labour contract, with the strongest form of the labour contract found in the Routine analytic class. ${ }^{33}$ It is plausible that the mortality rate in occupations regulated by a labour contract could be reduced in the linked records analysis by the exclusion of the Long-term unemployed from the relevant occupied NS-SEC classes.The differences in both the rules of assignment of NS-SEC by source and the capture of the Long-term unemployed are possible explanations for the somewhat higher mortality rate found among Large employers, higher managers and the lower rates for all other analytic classes in the linked records analysis. However, the difference between the classspecific rates produced by the two approaches is statistically significantly lower only for the Routine analytic class. The narrower gradient found in this analysis of linked records compared with that found using unlinked records is consistent with previous analysis of linked records in the four years immediately following the assignment of RGSC at the 1971 Census. ${ }^{6}$

Increasing the length of follow-up of men in the LS has been the traditional approach to mitigating the distorting impact of health selection out of the labour market, producing social gradients of mortality similar to decennial analyses. ${ }^{36,62,66}$ The approach adopted here of assigning the NS-SEC class from census records in 1991 for men allocated to an unoccupied NS-SEC in 2001 leaves a 40 per cent narrower gradient than that found in unlinked records. Comparison of allocations to the Routine analytic class at death showed 38 per cent were assigned to a higher NS-SEC at census, while allocations at census showed 32 per cent were assigned to a higher class at death. Consequently, there is a 20 per cent greater likelihood of demotion to the Routine analytic class at death than promotion from it, which may partly explain the lower rate found when assigning the death to the Routine analytic class at census, and hence the lower gradient.

Thirdly, the all-class mortality rate produced by the linked records analysis is lower than the unlinked records all-class mortality rate. Since the latter is based on all deaths registered to residents of England and Wales, it is assumed to be accurate. The observed difference does not appear to be due to sample variation, but may be influenced by loss to follow-up due to an unknown rate of unobserved emigration out of England and Wales, and the known under-enumeration at the 2001 Census. ${ }^{63}$ Because of the greater concentration of that under-enumeration in disadvantaged sections of the population, it is possible that the effect would again be to reduce the mortality gradient found across NS-SEC classes.

## Comparison with previous findings

The results reported here are largely consistent with an unlinked records analysis of mortality in 1991-93, ${ }^{3}$ which used an early version of NS-SEC90 (not identical to the version of NS-SEC90 used above to adjust for health selection). However, that analysis found a lower standardised mortality ratio among Small employers, own-account
workers compared with men working in Intermediate occupations. A separate analysis of mortality in 1991-95 of men in the LS who were present at the 1991 Census (not reported here) shows a similar though non-significant pattern. Neither of these analyses was able to make any allowance for health selection. This difference may therefore be due to the limited comparability of the classifications used, health selection effects, and/or changes over the intervening decade in the age and class distribution of the population. The latter possibility is supported by the fact that the proportion of men aged 60-64 in the LS sample who were allocated to the Small employers, own account workers analytic class increased from 11 per cent in 1991-95 to 18 per cent in 2001-04, while the proportion allocated to the Intermediate analytic class fell from 7 per cent to 5 per cent in the same period.

A reliable comparison with findings on social inequalities in mortality for previous time periods is difficult because of the change in socio-economic classification. The ratio of the mortality rates of the most advantaged and least advantaged NS-SEC analytic classes is of a similar magnitude to that found between the broadly equivalent RGSC classes in the preceding decade. The similarity of the ratio of 2.8 in 2001-03 to that of 2.9 in 1991-93 reinforces the strength of each classification to discriminate mortality risk by socio-economic status. The measurement of inequalities in mortality by RGSC was criticised for comparing the relatively small populations at each end of the socio-economic spectrum, which had limited relevance to the vast majority of the population assigned to the intervening classes. This NS-SEC analysis has demonstrated that the scale of inequality holds when comparison is extended to a larger group of occupations designated to the Routine analytic class, and suggests the gradient by RGSC found earlier is not simply an artefact of an ever diminishing, more disadvantaged population of men concentrated in social class V. The restriction of the study population to men aged 25-64 in 2001-03 together with the larger populations of men within the Large employers, higher managers and Routine analytic classes may be consistent with increasing social inequalities in adult male mortality; however, further analysis is needed to produce reliable comparisons over time between figures based on RGSC and those using NS-SEC.

## Limitations of the analysis

The age range of the study population ensured that the majority of men included would be in permanent employment in 2001, and could therefore be assigned to an occupied NS-SEC class. Because some of the steepest socio-economic gradients in adult mortality are those from accidents and violence in younger men, ${ }^{64,65}$ the lower age limit of 25 years may lead these results to understate the extent of inequalities in the adult male population as a whole.

The methods used were designed to reduce the artefactual effect of health selection out of the labour market. The possible substantive impact of health-related social mobility on social inequalities in mortality is a separate though related question, and can only be addressed through longitudinal analysis. Previous research using the LS data has indicated that selection in the latter sense was not a major cause of the well-established patterns in mortality by RGSC, but is likely to be a constraining factor. ${ }^{39,40,66}$ There is no apparent reason why such effects should have greater influence in analysis by NS-SEC, but future research will address this possibility.

This analysis has not addressed trends over time, except through the comparison of overall mortality gradient. Further analysis is required to provide a reliable basis for the comparison of mortality before and after the introduction of NS-SEC in 2001. Reporting of trends in life expectancy from the 1970s to date using RGSC, based on the LS only, will therefore continue to be of key importance for some time. The most recent update of the time series in life expectancy by RGSC covers the period 2002-05. ${ }^{67}$ Future research will also test the feasibility of
producing an inter-censal time series of mortality estimates by NS-SEC, using denominators based on national survey data.

## Conclusions

This analysis of adult male mortality by NS-SEC provides an indication of the health impact of different social and occupational circumstances in England and Wales during the early 21st century. The age-standardised mortality rate among men aged 25-64 in routine occupations in 2001-03 was found to be 2.8 times the rate among men working as Large employers, higher managers. While direct comparisons cannot be made with previous time periods because of the change in socio-economic classification, it is clear from these results that a substantial and consistent social gradient in mortality continues to be in evidence.

The methods used in this analysis involved detailed consideration of the sources of bias and other weaknesses in the individual data sources, and their likely impact on the calculation of mortality rates by socio-economic status. The methodological advantages of record linkage in the LS were used to adjust the unlinked records measurement, allowing greater confidence in the validity of the resulting estimates. The combination of unlinked and linked records approaches provides robust, statistically significant estimates of mortality for men in occupied NS-SEC classes.

The figures presented here based on the unlinked records approach are recommended for overall description of social inequalities in mortality in England and Wales and further disaggregation by cause of death and geographical area. The linked records approach, drawing on more complete and accurate assignment of individuals to NS-SEC classes, allows mortality in non-occupied groups to be estimated but is likely to underestimate the mortality of the least advantaged occupied men.

This analysis confirms the value of NS-SEC for the examination of mortality inequalities in men of working age. A clear social gradient in mortality can be distinguished whether using the nine, five, or three analytic class version of NS-SEC. Each class had a significantly different age-standardised mortality rate from the others within each version. The more condensed versions give a smaller, but still substantial, difference between the most advantaged and least advantaged groups.

## Key findings

- In 2001-03, the age-standardised mortality rate of men aged 25-64 in routine occupations was 513 per 100,000 population, 2.8 times the rate of 182 per 100,000 among men in higher managerial occupations
- The National Statistics Socio-Economic Classification (NS-SEC), which was introduced in 2001 to replace Registrar General's Social Classification (RGSC), provides a clear and consistent basis for the analysis of mortality in adult men
- There were statistically significant differences in mortality rates between all NS-SEC classes in a clear socio-economic gradient, whether using the full (nine class) or condensed (five or three class) version
- The mortality gradient found in this analysis is similar to the ratio of 2.9 times reported between men in unskilled manual occupations and professional men in 1991-93, based on RGSC
- Cross-sectional (unlinked records) analysis using death registrations and synthetic populations based on the 2001 Census and ONS annual population estimates, adjusted for biases identified in linked records in the ONS Longitudinal Study, can provide precise and robust estimates of mortality

## Box A1 Questions on occupation and employment in the 2001 Census

Answer the remaining questions for the main job you were doing last week, or if not working last week, your last main job.

- Your main job is the job in which you usually work the most hours

25 Do (did) you work as an employee or are (were) you self-employed?
$\lceil$ Employee
$\square$ Self-employed with employees
$\square$ Self-employed/freelance without employees
26 How many people work (worked) for your employer at the place where you work (worked)?

- If you are (were) self-employed, tick to show how many people you employ (employed)
$\Gamma$
1-9
$\Gamma$
10-24

「 25-499
$\Gamma$
500 or more

## 27 What is (was) the full title of your main job?

- For example, PRIMARY SCHOOL TEACHER, STATE REGISTERED NURSE, CAR MECHANIC, TELEVISION SERVICE ENGINEER, BENEFITS ASSISTANT
- Civil Servants, Local Government Officers - give job title not grade or pay band

28 Describe what you do (did) in your main job.

29 Do (did) you supervise any other employees?

- A supervisor or foreman is responsible for overseeing the work of other employees on a day-to-day basis

Yes
$\Gamma$
No

30 What is (was) the business of your employer at the place where you work (worked)?

- For example, MAKING SHOES, REPAIRING CARS, SECONDARY EDUCATION, FOOD WHOLESALE, CLOTHING RETAIL, DOCTOR'S SURGERY.
- If you are (were) self-employed/freelance or have (had) your own business, what is (was) the nature of your business?
- Civil Servants, Local Government Officers - please specify your Department

## Box A2 Recording of occupation and employment status at death registration

Occupation refers to the latest gainful employment followed by the person concerned up to the date of the birth, still-birth, death or marriage. This includes any job regularly engaged in, for whatever hours are regarded as normal, permanent or temporary in the particular occupation. Regular paid employment for a few hours a day is thus included. Unemployed persons should have their last gainful occupation recorded. If they have never worked, a line should be drawn through the space or column. Where the informant or person(s) to be married have a non-gainful occupation (e.g. Home duties) this may be recorded if requested. Retired persons should be described by reference to their last full-time occupation followed by the word 'retired' in brackets, e.g. 'Railway engine driver (retired)', 'Staff nurse (retired)'. Persons unable to work through ill-health or disability, should be described by their last gainful occupation; it is immaterial how long ago this was or whether incapacity is temporary or permanent. Where an informant to a death entry wishes an occupation to be recorded as 'Housewife/Househusband', 'Home Duties' or similar, this may be recorded. However, where the person in question was previously in gainful occupation, details of that occupation, with the informant's agreement, should be recorded.

Employment status is also elicited from the informant. Registrars ask whether the deceased was:

1. Employee not supervising others
2. Employee supervising others
3. Self-employed without employees
4. Self-employed with employees
5. No gainful occupation

These categories are then used to determine employment status in combination with the occupational details provided, in the following categories:
A. Employers (derived from occupation and category 4 above)
B. Self-employed, no employees (derived from category 3 above)
C. Manager (derived from occupation if SOC2000 code has prefix of 1 and category 2 reported above)
D. Supervisor (derived from occupation if SOC2000 code has prefix other than 1 and category 2 reported above)
E. Other employees (if category 1 reported above)
F. Pseudo-employment status code (if no gainful employment reported)

Categories 1 and 2 include directors, managers, foremen, gaffers, family workers, apprentices, trainees, etc, as well as all other persons employed by any person or company.

With regard to the identification of categories 1 and 2 as described above, descriptions such as manager, foreman, etc, may already be included in the occupation details supplied by the informant. There may be instances however where this will not be the case and in addition it will not be possible to deduce the applicable category from the stated occupation. In such circumstances an enquiry of the informant as to whether the occupation also carried responsibility for overseeing the work of other employees on a day-to-day basis, may enable the appropriate category to be established. Where information is not available and therefore the precise category cannot be determined, category 1 should be used.

Category 3 includes out-workers (persons working in their own homes for an employer), members of a partnership without paid employees, all parochial clergy, and all other self-employed persons, without paid employees.

Category 4 includes proprietors of businesses, medical and dental practitioners in general practice, and other self-employed persons provided they have paid employees or paid assistants.

Category 5 includes persons who have never had any occupations and are without private means.
Where 'housewife', 'househusband' or similar has been recorded in the register, completed with details of the person's last gainful occupation, the employment status applicable should reflect the last gainful occupation. The same applies where the person is unemployed or retired and the last gainful occupation is recorded in the register.

## Box A3 National Statistics Socio-Economic Classification - Operational categories and analytic classes

| Operational categories | Analytic classes |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Nine class version | Eight class version | Five class version | Three class version |
| L1 Employers in large organisations | 1.1 Large employers and higher managerial occupations | 1 Higher managerial and professional occupations | 1 Professional and managerial occupations | 1 Professional and managerial occupations |
| L2 Higher managerial occupations |  |  |  |  |
| L3 Higher professional occupations | 1.2 Higher professional occupations |  |  |  |

# Trends in cancer incidence by deprivation, England and Wales, 1990-2002 

Steve Rowan<br>Office for National Statistics

This article examines trends in cancer incidence by deprivation in England and Wales, and at the Government Office Region (GOR) and Wales level over the period 1990-2002.

The aim is to show whether the deprivation gap in cancer incidence between patients living in the least deprived areas and those in the most deprived has widened or narrowed over time for the three main cancers, breast (female), prostate and lung cancer.

The results show that the deprivation gap in lung cancer incidence has widened in the majority of GORs and Wales, particularly in males. For prostate cancer, where incidence was generally higher among those living in the least deprived areas, the deprivation gap has also widened in the majority of GORs and Wales.

## Introduction

Cancer is a major cause of morbidity in England and Wales. One in three people are diagnosed with cancer during their lifetime. ${ }^{1}$ However, cancer is predominantly a disease of the elderly, with only 0.5 per cent of all cancer cases diagnosed occurring in children aged $0-14$ and a peak in the age distribution occurring in the 70-79 age range. ${ }^{1}$ In 2004, in terms of both numbers and incidence rates, the most common cancers were prostate, breast (females), lung and colorectal (bowel) cancer. Together these cancers accounted for 50 per cent of all cases. ${ }^{2}$

Since 1971, England and Wales has had a population-based cancer registration system with 100 per cent geographical coverage and mechanisms in place to follow up cases. Hence more is known about the incidence of, and survival from, cancer than for most other diseases. In England, cancer registration is carried out by eight regional cancer registries who submit notifications to the Office for National Statistics (ONS). In Wales, cancer registration is carried out by the Welsh Cancer Intelligence and Surveillance Unit.

This is the first time trend analysis of cancer incidence by deprivation has been carried out by ONS. Analysis by area deprivation was last carried out for the years 1992-93 (combined), which only provided a snap shot of deprivation. ${ }^{1}$ At that time there was an inverse relationship between breast cancer and deprivation, with incidence rates for patients living in the least deprived areas being 30 per cent higher than in the most deprived areas. Similarly, prostate cancer incidence was around 45 per cent higher in the least deprived areas compared with the most deprived. In contrast, lung cancer was strongly associated with deprivation with incidence rates in the most deprived areas more than double those in the least deprived. There was no obvious association between incidence of colorectal cancer and deprivation.

This article analyses trends in cancer incidence for the three most common cancers - breast, prostate and lung - for which a relationship between incidence and deprivation had previously been observed in 1992-93. A question of interest is whether the gap in incidence for these cancers for patients living in the least deprived and the most deprived areas is widening or narrowing over time within the Government Office Regions of England (GOR), and Wales.

## Breast cancer

Breast cancer has always been the most common cancer in females. Since the 1970s there has been a gradual increase in incidence, which became more rapid from the late 1980s following the introduction of the NHS breast screening programme in 1988 (with full population coverage from around 1994). ${ }^{3}$

## Lung cancer

Lung cancer is more common in males than females. From a peak in the mid-1970s, incidence rates of lung cancer in men fell steadily. For women, however, the pattern of incidence is quite different, with changes in incidence lagging behind men by about 20 years and reaching a peak in the mid-1990s. ${ }^{3}$ The greatest risk factor for lung cancer is tobacco smoking, accounting for 90 per cent of cases in men and 80 per cent in women. ${ }^{4,5}$ The difference in patterns of incidence between men and women reflect historical differences between the two in terms of smoking habits. ${ }^{6}$

## Prostate cancer

Prostate cancer became the most common cancer in men in 1999. Incidence rates increased gradually from 1971, with a rapid increase between 1991 and 1994 and again from 1997. The latter is due to the increasingly widespread use of the prostate-specific antigen (PSA) test. ${ }^{3}$

## Data and methods

## Cancer incidence

Newly diagnosed cases of the three selected cancers for the period 1990-2004 were extracted from the National Cancer Registry database held at ONS on 26-27 February 2007. Variables required for analysis age at diagnosis, year of diagnosis and sex - were extracted along with others such as postcode, which were used to link to other datasets to obtain further variables.

## Population estimates

Population estimates were required for calculating cancer incidence rates. These were needed initially at ward level to enable linkage with deprivation scores. However, such population estimates were not available from official sources at ONS between censuses, that is, between 1991 and 2001, although 'experimental' population estimates at ward level had been produced for the years 2002-03. Since a population dataset over a longer time period was required, annual population estimates by five-year age-groups and sex at ward level for the years 1990-2002, fixed to the 2001 Census ward boundaries, were provided by Dr Paul Norman at the University of Leeds.

## Subnational variation by deprivation

It was decided to analyse at the GOR level of England, and Wales. At this level, it was envisaged that the datasets would contain sufficient numbers to enable analysis by deprivation level within region. The postcode subdirectory holds all postcodes in England and Wales linked to 2001 Census wards and GOR. This dataset was linked to the cancer dataset via the postcode variable.

Deprivation scores
Area-based deprivation indices, such as the one devised by Carstairs and Morris in the 1980s, measure material deprivation in small areas. ${ }^{7}$ The
first two sets of Carstairs scores were based on the results from the 1981 and 1991 Censuses respectively, and were calculated at Census ward level. Other deprivation indices, such as the Townsend Index and Indices of Multiple Deprivation (IMD), are also available. Carstairs scores were chosen for this analysis as they have been used widely in health research in $\mathrm{ONS}^{8,9,10}$ and elsewhere. ${ }^{11,12,13,14}$

Carstairs scores for the Census Area Statistics (CAS) wards in England and Wales have been used. The 2001 Carstairs scores for 8,844 wards each of which contain over 100 residents - out of the total of 8,850 wards were provided by Dr Paul Norman.

Carstairs scores are an un-weighted combination of four Census variables; namely, unemployment, overcrowding, car ownership and low social class (Social Class IV and V). In the 2001 Census, the National Statistics Socio-Economic Classification (NS-SEC) replaced Social Class. Therefore, Social Classes IV and V had to be approximated in order to derive the Carstairs scores. Each of the four component variables are first transformed or 'standardised' to a common scale (that is, with a mean of zero and standard deviation of one) so that the value of no one variable dominates the overall score. The scores range from positive (more deprived) to negative (less deprived) with the England and Wales average score set to zero. ${ }^{15}$

## Deprivation quintiles

On receipt of the 2001 Carstairs scores by Census wards, the corresponding 2001 population estimates (male and female combined) were attached via ward codes. The wards were sorted by score and divided into five groups (quintiles) according to equal fifths of the total population for England and Wales in 2001. Therefore, one fifth of the population was allocated to each deprivation category. Deprivation quintile $1(\mathrm{Q} 1)$ represents the fifth of the population living in the least deprived wards and deprivation quintile 5 (Q5) represents the fifth living in the most deprived wards.

## Methods

The analysis was carried out for three cancers, lung (male and female separately), breast (female) and prostate. The appropriate deprivation quintile was added to each individual cancer record (via the ward code) under the assumption that the deprivation quintile groups based on the deprivation scores as at 2001 had remained unchanged over the period 1990-2002.

Directly age-standardised incidence rates (ASRs) were used in the analysis to control for differences in the age structure of populations between geographical areas or over time. These were calculated for each GOR, and Wales, year of diagnosis and deprivation quintile using the European standard population together with 95 per cent confidence intervals. The age-groups $15-19,20-24, \ldots, 80-84,85+$ were used.

By dividing the ASR in the most deprived quintile by that in the least deprived (Q5/Q1), a rate ratio was obtained. For cancers of the breast and prostate - where incidence is higher in the least deprived, the ASR for Q1 was divided by that for Q5. This ratio was used to monitor whether a gap in incidence between the least deprived and most deprived was widening or narrowing over time. Confidence intervals ${ }^{16}(\mathrm{CI})$ at the 95 per cent level for the rate ratio of ASRs were also calculated (see Box One).

Analyses were originally carried out by single year of diagnosis, but results showed large random variation over time due to the relatively small number of cases used to derive some of the ASRs. This was particularly the case in GORs which had small proportions of the

## Box one

## Confidence Interval for rate ratio

$$
\mathrm{Cl}=\mathrm{R} \pm\left(1.96 \times \sqrt{\frac{1}{n_{1}}+\frac{1}{n_{5}}}\right)
$$

Where $\mathrm{R}=$ the ASR ratio $\mathrm{Q} / \mathrm{Q} 1$ (or Q1/Q5)
$\mathrm{n}_{1}=$ the total number of cases of cancer in Q1
$\mathrm{n}_{5}=$ the total number of cases of cancer in Q5
population classified as being in deprivation quintiles Q 1 or Q 5 . This resulted in the rate ratios also showing random variation. Therefore, it was decided to use three-year moving averages whereby ASRs were calculated using incidence and population numbers for 1990-92, 1991-93, ..., 2000-02. This had the effect of smoothing out the variation, without removing the essential patterns in the trends.

Because of clear deprivation gradients for all the cancers analysed, results presented here focus on comparing incidence rates for patients living in the least deprived and most deprived areas defined by deprivation quintiles Q1 and Q5, respectively. Confidence intervals at the 95 per cent level were produced to determine whether the differences between the ASR trend lines representing Q1 and Q5 were significant. If the CIs of two ASRs (at the same moment in time) do not overlap, then these two rates are significantly different at the 5 per cent level of significance. For the rate ratio trend line, if the CIs of two ratios (at two different time points on the line) do not overlap, then these two ratios are significantly different from each other.

## Presentation of results

For each cancer in turn, results are presented first to look at the overall pattern of geographical variation between and within GORs and Wales by combining data for all years from 1990-2002. This is followed by trend analysis, nationally and within each GOR and Wales, focusing on change over time in incidence rates in patients living in the least deprived (Q1) and most deprived (Q5) areas. This analysis informs the discussion on change in the deprivation gap over time for the three selected cancers.

## Results

## Breast cancer

The overall geographical pattern using 1990-2002 combined data showed that ASRs by deprivation quintile varied little between GORs. Within each GOR, ASRs were lowest for Q5 and highest for Q1, but the range of variation between quintiles was small (Figure 1).

Figure 1 Breast cancer: age-standardised incidence rates by deprivation quintile 1990-2002, females

Government Office Regions of England, Wales

In England and Wales, ASRs increased over the period 1990-2002 in both Q1 and Q5 although they were consistently higher in the least deprived compared to the most deprived quintile. This was broadly true at GOR level with the exception of East Midlands and Wales where there was no significant difference between Q1 and Q5 for the majority of the period (Figure 2).

In Q1, ASRs increased from the first half of the 1990s in all GORs except East of England and North East. In Wales, the incidence rates fell initially, but rose again from the mid-1990s to a level in 2000-02 similar to that found in 1990-92. In Q5, rates rose in North East, North West, Yorkshire and The Humber, East Midlands and West Midlands over the decade with no change in the remainder including Wales.

The ratio of ASRs (Q1/Q5), showed there was a significant increase over time only in London and South East GORs indicating the deprivation gap widened in just these two GORs and remained unchanged elsewhere (Figure A1).

## Lung cancer

Males
The overall geographical pattern using 1990-2002 combined data showed that ASRs for Q1 varied very little between GORs. However, for Q5, there was much more variation, with the highest incidence rate in North East and the lowest in East of England. As a consequence, the spread of ASRs by deprivation quintiles was wider than the England and Wales average in GORs in the north of England (North East and North West) and narrower in the south and east of England (East of England, London and South East) (Figure 3).

In England and Wales overall, over the period 1990-2002, ASRs decreased in both Q1 and Q5 although the rate in Q5 was around double that in Q1. This pattern is shared by all GORs and Wales, with the exception of East of England where there was no change in rates in Q5 over time (Figure 4).

The ratio of ASRs (Q5/Q1) increased between the early 1990s and 2000-02 in all GORs and Wales (from the mid-1990s in London) except for North West, Yorkshire and The Humber and West Midlands indicating that the deprivation gap has widened over time. This is because the rate of decrease in ASRs was greater in Q1 than in Q5 (Figure A2).

## Females

The overall geographical pattern using 1990-2002 combined data showed that ASRs for Q1 varied more between GORs than for males. For

## Figure 3 Lung cancer: age-standardised incidence rates by deprivation quintile, 1990-2002, males

Q5, the variation was similar to that for males, with the highest incidence rates in North East and lowest in East of England (Figure 5).

In England and Wales, ASRs decreased over the period in Q1, but increased in Q5. At GOR level, trends for females differed markedly from males with no change over time in the ASRs in Q1 - with the exception of South East where rates fell. In Q5, ASRs increased significantly in North West, Yorkshire and The Humber and East Midlands and decreased in London (Figure 6).

Between the early 1990s and 2000-02, the ratio of ASRs (Q5/Q1), increased for North West, East Midlands, West Midlands, South East and Wales, indicating the deprivation gap has widened over time in these areas (Figure A3).

## Prostate cancer

The overall geographical pattern using 1990-2002 combined data showed that ASRs varied little between GORs. The variation between deprivation quintiles was broadly similar across GORs, with higher rates in the less deprived. The exception to this is London where there was no variation in rates between deprivation quintiles (Figure 7).

Like breast cancer incidence rates in England and Wales over time, ASRs were consistently higher in the least deprived compared to the most deprived areas. However, at GOR level, ASRs for Q1 and Q5 were only

## Figure 5

Lung cancer: age-standardised incidence rates by deprivation quintile, 1990-2002, females

Government Office Regions of England, Wales

significantly different from each other over the whole period in North West and West Midlands and, with the exception of London (where there was no difference), significantly different in the remaining GORs and Wales from the late 1990s (Figure 8).

For Q1 the ASRs increased in all GORs and Wales over the period although the rate of increase was more pronounced from the mid-1990s when PSA testing was more widely used. The increase in rates in Q5 was more gradual with the exception of South West where there was no rise and West Midlands where the rise was similar to that for Q1 and London where the increase in the rate in Q5 was greater than the increase in Q1. The ratio of ASRs (Q1/Q5) - and thus the deprivation gap - increased between the early 1990s and 2000-02 in all GORs and Wales except West Midlands, London and East of England. This was because the rate of increase in incidence in Q1 was greater than in Q5 (Figure A4).

## Discussion

For investigations of the aetiology (causes and risk factors) of cancer and for health care planning, incidence is the measure of primary interest, whereas mortality data are useful in planning resources for palliative care and hospices.

For breast cancer, the deprivation gap is not widening (or narrowing) in the majority of GORs and Wales. Most risk factors relate to a woman's

## Figure 7 Prostate cancer: age-standardised incidence rates by deprivation quintile, 1990-2002

Government Office Regions of England, Wales

reproductive history such as early onset of menstrual periods, late first pregnancy and late menopause. ${ }^{6}$

The widening of the deprivation gap in lung cancer for males can be attributed to a greater decline in incidence in the least deprived areas compared to the most deprived. For lung cancer in females, however, the widening of the gap (where it occurs) is generally the result of an increase in incidence amongst the most deprived compared to no significant change over time in the least deprived. Since the latency period for lung cancers attributable to smoking is at least 20 years, any intervention programmes leading to a decrease in smoking prevalence would not have an immediate impact on lung cancer incidence rates. Also, the prevalence of smoking varied little across socio-economic groups before the dangers of smoking were recognised; currently, there are differences in the decline of smoking by social class. ${ }^{17}$

For prostate cancer the increase in incidence, particularly in the late 1990s, reflects the increasingly widespread use of the PSA test. The widening of the deprivation gap is the result of a greater increase in incidence amongst the least deprived and suggests the test is being utilised more by those living in these areas. However, the test detects asymptomatic prostate cancers in older men which would have gone undetected otherwise in their lifetime. The causes of prostate cancer are essentially unknown. Studies focusing on reproductive characteristics and

sexual habits have had inconsistent results. However, despite international differences in incidence, no specific causal factors such as environmental, lifestyle, diet or occupation have been conclusively identified. ${ }^{6}$

Many deprivation indices have been devised since the 1980s and some of the associated advantages and disadvantages have been discussed elsewhere. ${ }^{15}$ However, the choice of deprivation index for this article was governed by practical considerations. Since population estimates were required to calculate cancer incidence rates, it was decided to use a census-based deprivation index at ward level where population estimates on historically consistent boundaries were available.

In 2001, in South West, South East and East of England GORs, only 4 to 5 per cent of the population lived in the most deprived wards. London GOR only had 5 per cent of the population living in the least deprived wards. It has been suggested that deprivation indices tend to overestimate disadvantage in London. For example, car ownership is included in the Carstairs measure of deprivation, yet it could be argued that it is less likely to be an indicator of low income in central London (where transport links are plentiful) compared to rural areas ${ }^{18}$ (Table 1) (Figure A5).

As stated earlier, there was an assumption that the deprivation quintiles based on the deprivation scores as at 2001 remained unchanged over the

| Table 2 | Comparison of deprivation quintile assignments at ward level between 1991 and 2001 populations, percentages |  |  |

| South West | 61 | 37 | 2 |
| Wales | 62 | 36 | 2 |

whole period 1990-2002. In reality, wards allocated to a particular quintile in 1991 (using 1991 Carstairs scores also obtained from Dr Paul Norman) could be allocated to a different quintile in 2001 (using 2001 Carstairs scores). The extent to which wards are allocated to the same or different quintiles between censuses is given in Table 2. It shows that around twothirds of wards would be allocated to the same quintile at both censuses and one-third to a quintile either immediately above or below. However, the net error is likely to be small when the wards are aggregated to GOR level as they were in these analyses (Table 2).

When looking at deprivation, it should be noted that not everyone living in a deprived ward is socio-economically disadvantaged or that all those that are disadvantaged necessarily live in deprived wards. Factors such as this tend to dilute the underlying relationships at the individual level between the cancer incidence and socio-economic deprivation or any risk factors, such as smoking, for which deprivation is a marker.

## Key findings

- Over the period 1990-2002, the gap in incidence rates for breast cancer between those living in the least deprived areas (where incidence was generally higher) and those in the most deprived areas, widened in just London and South East GORs and remained unchanged elsewhere
- Over the same period, rates of lung cancer incidence decreased for males living in both the least and most deprived areas, but more rapidly in the former leading to a widening of the deprivation gap in the majority of GORs and Wales
- For lung cancer in females, the widening of the gap occurred in the North West, East Midlands, West Midlands, South East GORs and Wales and is generally the result of an increase in incidence amongst the most deprived compared to no significant change over time in the least deprived
- For prostate cancer, where incidence was generally higher in the least deprived areas, the deprivation gap widened in all GORs and Wales - except West Midlands, London and the East of England - as the result of a greater relative increase in incidence rates among men living in the least deprived areas

## Acknowledgements

These analyses would not have been possible without the provision of ward level population estimates and 1991 and 2001 Carstairs scores by Dr Paul Norman, School of Geography at the University of Leeds. Paul Norman's research, the Micro-geography of UK demographic change 1991-2001 (RES-163-25-0012) is funded under the ESRC's Understanding programme: see www.uptap.net/project01.html The National Cancer Intelligence Centre at ONS is grateful for all the work of the regional cancer registries in England and of the Welsh Cancer Intelligence and Surveillance Unit over the years that the national cancer registration scheme has been in operation.

APPENDIX

# Cancer survival indicators by Cancer Network: a methodological 

 perspectiveLibby Ellis, Bernard Rachet and<br>Michel P Coleman<br>London School of Hygiene and<br>Tropical Medicine

Cancer Networks are responsible for the management of cancer services in England. They are, in principle, logical units for the analysis of cancer survival, since for most patients, the entire pathway of referral, diagnosis and treatment is likely to be contained within the territory of a Cancer Network.

This study investigates the implications of using each patient's Cancer Network of residence as the geographic basis of cancer survival indicators for the Department of Health and the National Health Service. Incidence data from the National Cancer Registry were used to estimate survival from cancers of the breast and colon diagnosed in adults during 1996-98.

## Survival estimates varied little

 between Cancer Networks. They were generally stable over time. We conclude that Cancer Networks are suitable geographic units for the analysis of cancer survival as a NHS performance indicator.
## Introduction

Cancer survival statistics provide useful information about the local performance of the National Health Service (NHS) for the resident populations of the various health and administrative geographies in England. In the last few years, Government Office Regions (GOR) and Strategic Health Authorities (SHA) have been the main geographic basis for cancer survival indicators requested by the Department of Health and the National Health Service.

Until the most recent changes to NHS boundaries in April 2006, the 28 SHAs had overall strategic responsibility for the delivery of health care to their resident populations, averaging around two million. From April 2006, the 28 SHAs merged to form ten new SHAs, which resemble, at least in terms of size and boundary, the nine Government Office Regions.

The ten much larger SHAs that arose from these boundary changes are too large to demonstrate geographical variations in cancer survival to the requisite level of detail. The resident populations of the new SHAs range from about 2.5 to 7.5 million. ${ }^{1}$ The 152 newly configured Primary Care Trusts (PCTs), although much larger than the previous 302, are still too small to be used as geographic units for monitoring cancer survival. The smallest PCT has a resident population of just 90,000, and the statistical stability of survival estimates for such small areas is not adequate for reliable monitoring of performance. ${ }^{2}$

As a consequence of this re-organisation, Cancer Networks have been proposed as an alternative geographic unit for the comparison of cancer survival statistics.

In principle, Cancer Networks are more logical units of analysis for cancer survival than SHAs, since for the vast majority of cancer patients,
the entire patient pathway ${ }^{3}$ of referral, diagnosis and treatment will be contained within the territory of the Cancer Network in which they reside. There are currently 34 Cancer Networks, each serving a population of around one to two million people. Cancer Networks were established in 2001 under the NHS Cancer Plan. ${ }^{4}$ They bring together health service commissioners and providers, the voluntary sector and local authorities in a defined territory, and they are responsible for the entire range of cancer management services for the population of that territory.

Despite reconfiguration of a few boundaries in October 2002, Cancer Networks have been more or less stable since their creation in 2001. In a climate of frequently changing NHS administrative geography, comparison of cancer survival estimates with previous years can become meaningless when the geographical units of analysis no longer refer to the same population. The recent and likely future stability of the Cancer Networks should permit more reliable and more useful monitoring of geographical comparisons and temporal trends in cancer survival. (Note: a few mergers have in fact occurred among the 34 Cancer Networks in existence when this article was written.) In contrast to SHAs however, Cancer Network boundaries are not always coterminous with GORs and do not easily aggregate to them, or indeed to any other health or administrative geography.

The populations covered by Cancer Networks are large (1-2 million people), and comparable with those covered by population-based cancer registries in many other countries. Statistical stability of cancer survival indicators will be greater than for smaller geographic units, such as PCTs.

Although the number of Cancer Networks in England today (34) is similar to the number of SHAs up to 2006 (28), the range of resident population sizes differs significantly. The smallest SHA had a resident population of approximately 1.15 million, but seven of the 34 Cancer Networks have a resident population of fewer than one million (Table 1). Cancer Networks have a five-fold range in population size.

Given the comparatively small population in some Cancer Networks, this article explores the stability of one- and five-year survival estimates for two common cancers, and examines the extent to which the Cancer Network of residence can be reliably used as the geographic basis for NHS cancer survival indicators.

## Methods and data

The incidence data used in this article are taken from the National Cancer Registry at the Office for National Statistics (the National Cancer Intelligence Centre). The analysis included adults (15-99 years) resident in each of the 34 Cancer Networks in England who were diagnosed with cancer of the breast (women only, ICD-10 code C50) or colon (men and women, ICD-10 code C18) during 1996-98, and were followed up until 31 December 2003. Data on at least five years of follow-up were available for all patients included in the analyses.

Cancer registration in England is conducted by eight regional registries which collect and collate data on cancers resident in their area, and submit a standard dataset on these registrations to the National Cancer Intelligence Centre. All adults resident in England who were diagnosed during 1996-98 with breast or colon cancer as a first, primary, invasive, malignant neoplasm were eligible for inclusion in the analysis. Records of benign and in situ tumours, and those of uncertain behaviour, were considered ineligible. Patients known to have had a previous invasive primary malignancy at any site (except non-melanoma skin cancer) at any time since 1971 were excluded.

## Relative survival

One- and five-year relative survival estimates for England by age and calendar year of diagnosis were estimated. Relative survival is the ratio of the observed (absolute) survival of the cancer patients and the survival that would have been expected if those patients had experienced only the same age- and sex-specific mortality rates (background mortality) as the general population from which they are drawn. It provides a measure of patient survival corrected for the effect of independent causes of death, other than the cancer of interest. The background mortality is derived from life tables. Since background mortality varies substantially between regions of the country, and in certain age ranges such variations are wide, we used separate life tables for each region in our survival analysis. Complete life tables by single year of age (up to 99 years), sex and region (GOR) were derived from the numbers of deaths in England during the period 1997-99 and from mid-year population estimates for 1998. ${ }^{5}$ These life tables were used to represent background mortality in England during the period 1996-2003.

The maximum likelihood approach for individual records was applied to estimate both observed and relative survival, ${ }^{6,7}$ using an algorithm

## Box one

#### Abstract

Relative survival is the ratio of the survival actually observed in the cancer patients, and the survival that would have been expected if they had only experienced the same mortality rates, in the calendar period in question, at each age and for each sex, as those observed in the general population from which they are drawn. ${ }^{6,7,9,10}$ It is usually expressed as a percentage (For example, $0.6 / 0.8=75$ per cent). It can be interpreted as the proportion of survivors after correction for other causes of death. The general population (background) mortality rates are taken from life tables. Cancer Survival Trends ${ }^{11}$ should be consulted for further details of the methods. The proportion of survivors who have a normal life expectancy (the proportion 'cured') would be the ideal outcome measure, but methods remain under development, and relative survival estimates at one and five years have become the conventional measures of short- and medium-term outcome of cancer treatment.

developed for previous analyses. ${ }^{8}$ Survival was estimated within threemonth intervals for the first six months, then the second six-month period, separately for the second and third years, and for the fourth and fifth years combined. We report relative survival at one and five years after diagnosis.

## Statistical reliability

The statistical precision of survival estimates depends on the number of events (deaths) that contribute to the estimate. This depends in turn both on the number of patients diagnosed (which depends on the incidence rate and the size and age-sex structure of the underlying population) and on the lethality of the tumour, which changes with time since diagnosis, but also varies with age and sex, and over calendar time, as well as between geographic areas. We explored the range and variability between Cancer Networks in the number of deaths for each cancer included in the analysis (those occurring within five years of diagnosis) as a guide to the reliability of the survival estimates.

We estimated the relative survival for each calendar year as well as for the three-year period 1996-98 for each cancer. The stability of the survival estimates across the three years of incidence was assessed as a measure of 'external' reliability. We used the median value as a measure of central tendency among the 34 estimates of survival, and the interquartile range or IQR (which includes 50 per cent of observed values between the 25 and 75 centiles of the distribution) to reflect variation.

We used two measures to explore the 'internal' reliability of the survival estimates: the distribution of their standard errors and the coefficient of variation. The coefficient of variation (CV) expresses the standard deviation of the survival estimates for the set of Cancer Networks as a percentage of the overall mean value, and is a measure of their dispersion.

We also estimated the temporal reliability of time trends in survival by examining year-to-year fluctuation in the survival estimates. This fluctuation in survival for each Cancer Network is quantified as the average of the two successive absolute differences between the survival estimates for patients diagnosed in 1996 and 1997, and those diagnosed in 1997 and 1998. For example, for three successive estimates of 61.0 per cent, 62.0 per cent and 60.2 per cent, the value would be 1.4 percentage points (the mean of 1 percentage point and 1.8 percentage points, ignoring the sign of the difference). We present the mean and interquartile range of year-to-year fluctuations for the 34 Cancer Networks.

## Results

## Number of deaths

The median number of deaths within five years of diagnosis among patients diagnosed with breast or colon cancer during the period 1996-98 that could be included in the analysis was roughly one-third smaller for Cancer Networks than for (pre-2006) SHAs. There were approximately 90 fewer deaths per year from breast cancer, and 35 fewer deaths per year from colon cancer in each Cancer Network compared with the SHAs (Table 2). The interquartile ranges were slightly narrower for Cancer Networks compared to SHAs.

The difference in the number of deaths within five years of diagnosis between Cancer Networks ( $\mathrm{n}=34$ ) and Strategic Health Authorities $(\mathrm{n}=28)$ is a consequence of the different resident population sizes.

## Box two

To summarise the variability of a set of survival estimates, we divide the entire range of values, from highest to lowest, into centiles (one-hundredths). The median is the value at the middle of the distribution (the central tendency) and is thus the 50 centile value. The interquartile range is one measure of the dispersion of the estimates (how widely they range around the median), and is the range between the 25 and 75 centiles of the distribution. The standard error is another measure of the dispersion of the observed values around the central value (mean, or average). The coefficient of variation is a standardised measure of this dispersion, expressed as a percentage, which does not depend on the actual value of the average.

## 'External reliability'

For breast cancer in women, the median one- and five-year relative survival estimates among the 34 Cancer Networks improved steadily by approximately $1.0-1.5$ percentage points between successive years of incidence 1996, 1997 and 1998. Median one-year survival estimates increased by 0.7 percentage point (from 93.8 per cent to 94.5 per cent) between 1996 and 1997, and by 0.6 percentage point (from 94.5 per cent to 95.1 per cent) between 1997 and 1998. For five-year survival, estimates increased by 1.6 percentage points (from 78.8 per cent to 80.4 per cent) between 1996 and 1997, and by 1.0 percentage point (from 80.4 per cent to 81.4 per cent) between 1997 and 1998 (Table 3). This steady pattern of improvement of survival estimates is consistent with the national picture.

| 1996 | 66.1 | 62.1 | 70.1 | 46.2 | 42.5 | 49.8 |
| 1997 | 64.9 | 62.3 | 69.4 | 46.5 | 43.0 | 48.4 |
| 1998 | 66.7 | 63.8 | 69.9 | 48.1 | 44.3 | 51.7 |
| 1996-98 | 66.6 | 63.4 | 68.8 | 47.0 | 43.6 | 48.6 |

Note: Relative survival is the ratio of the survival actually observed in the cancer patients and the survival of the general population, expressed as a percentage.

For colon cancer in each sex, the year-on-year survival estimates were slightly more variable. For example, median one-year survival estimates in men decreased by 1 percentage point (from 68.5 per cent to 67.5 per cent) between 1996 and 1997, and then increased by 2.7 percentage points (from 67.5 per cent to 70.2 per cent) between 1997 and 1998. The interquartile ranges also reflect this variability: they were wider for colon cancer than for breast cancer (Table 3).

## 'Internal reliability'

For survival estimates based on a single year of diagnosis, the median standard error of the estimates among the 34 Cancer Networks for oneyear survival for women with breast cancer was around 0.9 , with very little variation (IQR 0.8-1.1). For colon cancer, median standard errors of the annual estimates were around 3.5 in each sex, again with little variation (IQR 2.9-4.1). For five-year survival, the median standard error was about 1.7 (IQR 1.4-2.0) for breast cancer in each of the three years, and about 4.2 (IQR 3.5-5.0) for colon cancer in each sex (Table 4).

| Table 4 | Distribution of the standard error of relative survival estimates in 34 Cancer Networks, by sex and year of diagnosis: adults (15-99 years) diagnosed 1996-98 |  |  |  |  |  |  |  |

| 1996-98 | 2.0 | 1.8 | 2.3 | 3.1 | 2.4 | 2.1 | 2.6 | 5.1 |

Note: The standard error is a measure of the dispersion of the observed values around the central value (mean, or average).

Survival estimates based on a three-year period (1996-98) were more precise than the annual estimates, with median standard errors of 0.6 and 1.0 for women with breast cancer (for one- and five-year survival respectively), and of 2.0 and 2.5 for colon cancer in each sex. Variability between Cancer Networks was about half that observed for annual estimates, with very narrow interquartile ranges (Table 4).

Variability in the annual estimates of one- and five-year survival in the 34 Cancer Networks was small, with a coefficient of variation of 1 per cent and 2 per cent for breast cancer, and of 5 per cent and 9 per cent for colon cancer. The use of three years of data reduces this variability still further. For breast cancer, the coefficient of variation falls from 1 per cent to 0.6 per cent for one-year survival and from 2 per cent to 1 per cent for five-year survival. For colon cancer, the coefficient of variation falls from 5 per cent to 3 per cent for one-year survival and from 9 per cent to 5 per cent for five-year survival (Table 4).

## 'Temporal reliability'

Table 5 shows the year-to-year fluctuation (percentage) in one- and five-year relative survival estimates in the 34 Cancer Networks. This is estimated as the average of the absolute difference (whether positive or negative) in the survival estimates for successive years for a given Cancer Network. For example, a change from 61.0 per cent (1996) to 62.0 per cent (1997) to 60.2 per cent (1998) would imply a change of +1 percentage point and then -1.8 percentage points, for which the mean annual change would be 1.4 percentage points.

The average year-to-year fluctuation in one- and five-year relative survival was around 2 per cent for breast cancer in women and around

Note: Estimated as the average of the absolute difference (whether positive or negative) in the survival estimates for successive years for a given Cancer Network. For example, a change from 61.0 per cent (1996) to 62.0 per cent (1997) to 60.2 per cent (1998) would imply a change of +1 per cent and then -1.8 per cent, for which the mean annual change would be 1.4 per cent. The table shows the mean and interquartile range among the 34 estimates of this annual fluctuation, for both one- and five-year survival estimates.

5 per cent for colon cancer in both men and women (Table 5). Annual survival estimates for individual Cancer Networks, based on single years of diagnosis, fluctuate much more for colon cancer than for breast cancer. This instability of time trends in survival has implications for the use of annual survival estimates as performance indicators.

The national rankings of individual Cancer Networks on the basis of survival estimates derived from single years of diagnosis were not stable. Rankings fluctuate widely for a small year-on-year change in survival. For example, the annual change in rank for one-year breast cancer survival was dramatic (Figure 1), despite the fact that the example concerns the most steady trend. One Cancer Network, which had the lowest survival for breast cancer in 1996, was ranked second highest in 1998.

## Discussion

As previously discussed, Cancer Networks are similar in number to the 'old' SHAs, and the survival estimates presented here, for patients diagnosed during 1996-98, are comparable to those published for the 28 Strategic Health Authorities for the same period. ${ }^{12}$

The range of survival estimates for breast and colon cancer in the 34 Cancer Networks in existence at the time of these analyses is fairly narrow, but year-to-year fluctuation in survival estimates occurs within individual Cancer Networks for colon cancer, much more than for breast cancer. Since the annual number of new breast cancer cases is approximately twice that of colon cancer, it will be necessary to aggregate at least two years of colon cancer incidence data to obtain statistically stable results for individual Cancer Networks. Although annual indicators derived from data aggregated over two or more years will overlap in time coverage, which could mask recent changes in survival, it is far more important to ensure that reliable estimates of survival are used in the assessment of trends. This has important implications for the interpretation of time trends, especially as it is intended that cancer survival indicators will be updated annually.

This approach can be used with other common cancers but cannot be extended to every cancer, no matter how rare. It is not possible to give explicit guidance for every cancer. This is because the statistical robustness of cancer survival depends on the number of deaths included in the estimate, which depends in turn both on the number of cases (incidence) and the lethality of the tumour (survival), and both of those quantities are subject to geographic variation and to change over time. We chose to examine survival from breast and colon cancer in part because they are common, but also in part because they may be considered as 'sentinel' cancers from the perspective of performance management, since the efficiency of the entire patient pathway from early diagnosis to

Fluctuations in the national ranking of 34 Cancer Networks by one-year relative survival, breast cancer (women), by year of diagnosis 1996-98

England
National ranking of Cancer Networks by survival estimates for 1996

National ranking of Cancer Networks by survival estimates for 1997

National ranking of Cancer Networks by survival estimates for 1998

Note: Cancer Networks are labelled (numerically) according to their rank in 1996. The Cancer Network highlighted was ranked 1 (lowest) in 1996, 12 in 1997, and 33 (second highest) in 1998.
prompt referral and rapid access to optimal treatment are all known to be of signal importance in achieving optimal outcomes.

The national rankings of individual Cancer Networks on the basis of survival estimates derived from single years of diagnosis were not stable. Rankings can fluctuate widely for a small year-on-year change in survival, because the range of survival estimates between the 34 Cancer Networks is relatively narrow.

Ranking of the Cancer Networks within each of the nine GORs would be even more problematic. There are only a few Cancer Networks in any GOR, and their boundaries are not always coterminous. Ranking of Cancer Networks within a Government Office Region is not advisable.

Previous recommendations that cancer survival indicators for NHS geographies should be ranked within their NHS region (or current equivalent), rather than on a national scale, were based on data for Health Authorities in the 1990 s, when there were around 100 such areas. ${ }^{13}$ The instability of ranking the 34 Cancer Networks by survival estimates on a national scale is likely to be alleviated by the aggregation of several years of incidence data, because of improved statistical stability. The disadvantage is the interpretation of time trends in the indicator values.

Because survival may differ by age, and the age distribution of cancer patients may be dependant on both time and geography, the agestandardisation of cancer survival estimates is often necessary to enable comparisons to be made between different geographical areas (that is, Cancer Networks and SHAs), and over time. However, given the comparatively small population of some Cancer Networks, it was not possible to use conventional age standardisation as this requires an estimate of survival for each defined age group. Further work is in progress to explore the feasibility of age-adjusting relative survival estimates for Cancer Networks using Hermann Brenner's alternative approach for less common cancers, or common cancers in small areas. ${ }^{14}$

It should be clear from this discussion that the level and/or the ranking of cancer survival estimates for a given geographic area is not interpretable as a measure of performance in isolation. Persistently low ranking for survival from one cancer, or low ranking for several different cancers, should be used as a warning to seek explanations, and complementary information from other sources.

## Conclusion

Cancer Networks are suitable as the geographic basis for cancer survival indicators to be used in NHS performance management.

## Key findings

- Cancer Networks are logical units for the analysis of cancer survival. Survival estimates varied little between Cancer Networks and were stable over time. Cancer Networks should become the preferred geographic unit for the analysis of cancer survival as a NHS performance indicator
- Within individual Cancer Networks, the year-to-year fluctuation in estimates of cancer survival requires aggregation of at least two years of incidence data to obtain statistically stable results. Such estimates can be used as a performance indicator to show improvement over time within a given Cancer Network
- The national rankings of individual Cancer Networks on the basis of survival estimates using single years of diagnosis were not stable. For the purpose of bench-marking indicators, that is, to show the position of a given Cancer Network relative to other Cancer Networks, survival estimates should be based on at least three years of diagnosis, even for common cancers
- Cancer Networks should not be identified as 'poor performers' solely on the basis of a low national rank in survival for one particular type of cancer in a given year or period

## Acknowledgements

This report, and more generally the utility of cancer survival data for performance management in the National Health Service, would not have been possible without the extraordinary dedication of cancer registry staff in all the regional cancer registries in England in ensuring complete and accurate data collection over many years, and we are happy to ensure due recognition of the importance of their work here.

## StatBase ${ }^{\circledR}$

Health Statistics Quarterly tables are now available on StatBase ${ }^{\circledR}$ which can be accessed
via our website www.statistics.gov.uk

## Symbols

> ..$\quad$ not available
> $: \quad$ not applicable
> $-\quad$ nil or less than half the final digit shown
> blank not yet available

## Notes to tables

## Time series

For most tables, years start at 1971 and then continue at five-year intervals until 1991. Individual years are shown thereafter. If a year is not present the data are not available.

## United Kingdom

The United Kingdom comprises England, Wales, Scotland and Northern Ireland. The Channel Islands and the Isle of Man are not part of the United Kingdom.

## Population

The estimated resident population of an area includes all people who usually live there, whatever their nationality. Members of HM and US Armed Forces in England and Wales are included on residential basis wherever possible. HM Forces stationed outside England and Wales are not included. Students are taken to be resident at their term time addresses.

Further information on population estimates can be found on the National Statistics website at www.statistics.gov.uk/popest

## Live births

For England and Wales, figures relate to the number of births occurring in a period; for Scotland and Northern Ireland, figures relate to births registered in a period. By law, births must be registered within 42 days in England and Wales, within 21 days in Scotland, and within 42 days in Northern Ireland. In England and Wales, where a birth is registered later than the legal time period, and too late to be included in the count for the year of occurrence, it will be included in the count for the following year.

## Perinatal mortality

In October 1992 the legal definition of a stillbirth was changed, from a baby born dead after 28 completed weeks of gestation or more, to one born dead after 24 completed weeks of gestation or more.

## Period expectation of life

The life tables on which these expectations are based use death rates for the given period to describe mortality levels for each year. Each individual year shown is based on a three-year period, so that for instance 1986 represents 1985-87. More details can be found at www. gad.gov.uk/life_tables/interim_life_tables.htm

## Deaths

Figures for England and Wales relate to the number of deaths registered in each year up to 1992 , and the number occurring in each year from 1993, though provisional figures are registrations. Figures for both Scotland and Northern Ireland relate to the number of deaths registered in each year.

## Coding cause of death

Between 1 January 1984 and 31 December 1992, ONS applied its own interpretation of
the International Classification of Diseases Section Rule 3 in the coding of deaths where terminal events and other 'modes of dying' such as cardiac arrest, cardiac failure, certain thrombembolic disorders, and unspecified pneumonia and bronchopneumonia, were stated by the certifier to be the underlying cause of death and other major pathology appeared on the certificate. In these cases ONS Rule 3 allowed the terminal event to be considered a direct sequel to the major pathology and that primary condition was selected as the underlying cause of death. Prior to 1984 and between 1 January 1993 and 31 December 2000, such certificates were coded to the terminal event. National Statistics also introduced automated coding of cause of death in 1993, which may also affect comparisons of deaths by cause from 1993. Further details can be found in the annual volumes Mortality statistics: Cause 1984, Series DH2 no. 11, and Mortality statistics: Cause 1993 (revised) and 1994, Series DH2 no. 21.

From 1 January 2001, under ICD-10, Rule 3 has again been changed - for details see the article in Health Statistics Quarterly no. 13. This has resulted in a fall in the death rates from respiratory diseases, notably pneumonia, and consequently slight rises in the rates for other causes eg. strokes. For details of the major changes between ICD-9 and ICD-10, see the articles in Health Statistics Quarterly 08, 13 and 14.

## Age-standardised mortality rates

Directly age-standardised rates make allowances for changes in the age structure of the population. The age-standardised rate for a particular condition is that which would have occurred if the observed age-specific rates for the condition had applied in a given standard population. Tables 2.2 and 6.3 use the European Standard Population. This is a hypothetical population standard which is the same for both males and females allowing standardised rates to be compared for each sex, and between males and females.

## Abortions

Figures relate to numbers occurring in a period.

## Calculating quarterly rates

The denominators used for calculating quarterly rates for births, conceptions and abortions have been produced from mid-year population estimates and projections by linear interpolation.

## Marriages and divorces

Marriages are tabulated according to date of solemnisation. Divorces are tabulated according to date of decree absolute. In Scotland a small number of late divorces from previous years are added to the current year. The term 'divorces'
includes decrees of nullity. The fact that a marriage or divorce has taken place in England, Wales, Scotland or Northern Ireland does not necessarily mean that either of the parties is resident there.

## Civil Partnerships

The Civil Partnership Act 2004 came into force on 5 December 2005 in the UK, the first day couples could give notice of their intention to form a civil partnership. The first day that couples could normally form a partnership was 19 December 2005 in Northern Ireland, 20 December 2005 in Scotland and 21 December 2005 in England and Wales.

Civil partnerships are tabulated according to date of formation and area of occurrence. The fact that a civil partnership has taken place in England, Wales, Scotland or Northern Ireland does not necessarily mean either of the parties is resident there.

## Sources

Figures for Scotland and Northern Ireland have been provided by the General Register Office for Scotland and the Northern Ireland Statistics and Research Agency respectively.

## Rounding

All figures are rounded independently; constituent parts may not add to totals. Generally numbers and rates per 1,000 population are rounded to one decimal place (eg 123.4); where appropriate, for small figures (below 10.0), two decimal places are given (eg 7.62). Figures which are provisional or estimated are given in less detail (eg 123 or 7.6 respectively) if their reliability does not justify giving the standard amount of detail. Where figures need to be treated with particular caution, an explanation is given as a footnote.

## Latest figures

Figures for the latest quarters and years may be provisional and will be updated in future issues when later information becomes available.
Where figures are not yet available, cells are left blank.

## Iote

Estimated population (mid-year), live birth and death rates up to the latest available data, as given in the United Nations Monthly Bulletin of Statistics (May 2007), the United Nations Demographic Yearbook system, and the Eurostat Yearbook 2006 (May 2007).

Republic of Cyprus - Greek Cypriot controlled area only
Including former GDR throughout.
3 Greece - mid-year population excludes armed forces stationed outside the country but includes alien forces stationed in the area.
Malta - including work and resident permit holders and foreigners residing in Malta.
Poland - excluding civilian aliens within the country but including civilian nationals temporarily outside the country. Average year data for 2000 and 2001 contain revised data according to the final results of the population census 2002
Portugal - including the Azores and Madeira islands
7 Spain - including the Balearic and Canary Islands.
The European Union consists of 25 member countries (EU25) - 1 May 2004 (10 new member countries).
9 Including the Indian held part of Jammu and Kashmir, the final status of which has not yet been determined.
10 Japan - excluding diplomatic personnel outside the country and foreign military and civilian personnel and their dependants stationed in the area. Rates are based on births to or deaths of Japanese nationals only.

11 USA - excluding armed forces overseas and civilian citizens absent from the country for extended periods.
122002 to 2005 mid-year population estimates for the United Kingdom have been updated to include the latest revised estimates that take into account improved estimates of international migration
13 Indicates population estimates of uncertain reliability.
14 Figures were updated taking into account the results of the 2002 All Russian Population Census.
15 Mid-year estimates have been adjusted for under-enumeration
16 For statistical purposes the data for China do not include those for the Hong Kong SAR, Macao SAR and Taiwan province of China. Data for the period 1996 to 2000 have been adjusted on the basis of the Population Census of 2000. Data from 2001 to 2004 have been estimated on the basis of the annual national sample surveys of Population Changes. Estimate of uncertain reliability. Death rates for 1999-2003 and birth rates for 2000-2003 were obtained by the Sample Survey of Population Change 2003 in China.
17 Rate is for 1990-1995
18 As at 1 January - Eurostat Yearbook 2006 (May 2007).
19 Data refer to 15 April.
p provisional.

12002 to 2005 mid-year population estimates for England and Wales and the United Kingdom have been updated to include the latest revised estimates that take into account improved estimates of international migration.
2 National projections based on mid-2006 population estimates.
3 Between 2010 and 2020, state retirement age will change from 65 years for men and 60 years for women to 65 years for both sexes.
Between 2024 and 2026, state pension age will increase from 65 years to 66 years for both men and women.

Table 1.3
Population: subnational

[^2]12002 to 2005 mid-year population estimates for England and Wales and the United Kingdom have been updated to include the latest revised estimates that take into account improved estimates of international migration.
2 These projections are based on the revised mid-2004 population estimates and are consistent with the 2004-based national projections produced by the Government Actuary's Department.
3 Between 2010 and 2020, state retirement age will change from 65 years for men and 60 years for women to 65 years for both sexes.
Between 2024 and 2026, state pension age will increase from 65 years to 66 years for both men and women

Note: Death figures for England and Wales represent the number of deaths registered in each year up Birth and death rates from 2002 to 2005 have been updated to include the latest revised midto 1992, and the number of deaths occurring in each year from 1993 to 2005. Provisional death figures for 2006 and 2007 relate to registrations.
Birth and death figures for England and also for Wales each exclude events for persons usually
Birth and death figures for England and also for Wales each exclude events for persons usuats England and Wales. These events are, however, included in the totals for
resident outside England and Wales. These events are, howe
England and Wales combined, and for the United Kingdom.
From 1981 births to non-resident mothers in Northern Ireland are excluded from the figures for Northern Ireland, and for the United Kingdom. year population estimates that take into account improved estimates of international migration Birth and death rates for 2007 are based on the 2006-based population projections for 2007 Marriage and divorce rates in England and Wales for 1986 have been calculated using the interim revised marital status estimates (based on the original mid-2001 estimates) and are subject to further revision
Marriage, civil partnership and divorce rates in England and Wales for 2006 and 2007 are based on 2005 marital status estimates. Rates for Scotland for 2007 are based on 2006 marital status estimates.

Note: Death figures for England and Wales represent the number of deaths registered in each year up to 1992, and the number of deaths occurring in each year from 1993 to 2005. rovisional death figures for 2006 relate to registrations.
Birth and death figures for England and also for Wales each exclude events for persons usually resident outside England and Wales. These events are, however, included in the total for the United Kingdom. From 1981 births to non-resident mothers in Northern Ireland are excluded from the figures for Northern Ireland, and for the United Kingdom. Period expectation of life data for the United Kingdom, England and for Wales for 2001 to 2005 is based on death registrations and revised population estimates for 2002 to 2005.
Percentage of children under 16 to working-age population (males 16-64 and females 16-59).
Percentage of males 65 and over and females 60 and over to working-age population (males 16-64 and females 16-59).

TFR (total fertility rate) is the number of children that would be born to a woman if current patterns of fertility persisted throughout her childbearing life. It is sometimes called th TPFR (total period fertility rate)
4 Standardised to take account of the age structure of the population.
Unstandardised and therefore takes no account of the age structure of the population.
Per million population. The age-standardised mortality rate makes allowances for changes in the age structure of the population. See Notes to tables.
7 Deaths at age under one year per 1,000 live births.
82002 to 2005 mid-year population estimates for England and Wales and the United Kingdom have been updated to include the latest revised estimates that take into accoun improved estimates of international migration.
p provisional

[^6]1 Unstandardised and therefore takes no account of the age structure of the population.
2 Standardised to take account of the age structure of the population. This measure is more appropriate for use when analysing trends or making comparisons between different geographies.
3 TFR (total fertility rate) is the number of children that would be born to a woman if current patterns of fertility persisted throughout her childbearing life. It is sometimes called the TPFR (total period fertility rate).
4 Births per 1,000 women in the age-group; all quarterly age-specific fertility rates are adjusted for days in the quarter. They are not adjusted for seasonality.
5 Birth and rates from 2002 to 2005 have been updated to include the latest revised mid-year population estimates that take into account improved estimates of international migration.
6 Birth rates for 2007 are based on the 2006-based population projections for 2007.
p provisional.

Table 3.2
Live births outside marriage: age of mother and type of registration
England and Wales
Numbers (thousands), mean age and percentages

|  | Age of mother at birth |  |  |  |  |  |  | Mean age ${ }^{1}$ (years) | Age of mother at birth |  |  |  |  |  |  | Registration ${ }^{2}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Note: Conception figures are estimates derived from birth registrations and abortion notifications.
Rates for women of all ages, under 16, under 18, under 20 and 40 and over are based on the population of women aged 15-44, 13-15, 15-17, 15-19 and 40-44 respectively. For a quarterly analysis of conceptions to women under 18 for local authority areas see the National Statistics website, www.statistics.gov.uk
Figures for conceptions by age for the March and June quarters for 2006 exclude maternities where the mother's age was not recorded.
2 Conception rates from 2002 to 2005 have been updated to include the latest revised mid-year population estimates that take into account improved estimates of international migration.
p provisional

Abortions: residents and non-residents; age and gestation (residents only)

Note: Figures from 1981 are calculated from the population estimates revised in the light of the 2001 Census. All figures are based on a three-year period.
1 Figures for 2001 to 2005 for the United Kingdom, England and Wales, England and for Wales are based on revised population estimates for 2002-2005 and death registrations.
p provisional

Note: Figures represent the numbers of deaths registered in each year up to 1992 and the numbers of deaths occurring in each year from 1993 to 2005 . Provisional figures for 2006 and 2007 relate to registrations.
Death rates from 2002 to 2005 have been updated to include the latest revised mid-year population estimates that take into account improved estimates of international migration.
Rates per 1,000 live births.
2 Death rates for 2006 have been calculated using the mid 2006 population estimates published on 22 August 2007.
3 Death rates for 2007 are based on the 2006-based population projections for 2007.
p provisional

Note: Figures represent the numbers of deaths occurring in each year with the exception of provisional figures for 2006 and 2007 which relate to registrations.
Death rates from 2002 to 2005 have been updated to include the latest revised mid-year population estimates that take into account improved estimates of international migration.
1 Total deaths rates for 2006 and 2007 have been calculated using the mid-2006 population estimates published on 22 August 2007.
p provisional.

## Report:

# Deaths related to drug poisoning in England and Wales, 2002-06 

## Introduction

This report presents the latest figures from the Office for National Statistics (ONS) database of deaths from drug-related poisoning in the period 2002 to 2006, and includes new data for 2006. The database contains information on deaths from 1993, and results based on registrations of deaths in each calendar year from 1993 to 2005 were published in a previous report in Health Statistics Quarterly. ${ }^{1}$ Since the publication of that report, mid-year population estimates for 2002 to 2005 have been revised. Mortality rates for those years have therefore been calculated with the revised estimates in this report.

## The database

The database of deaths related to drug poisoning has been developed to facilitate research into these deaths and to aid the identification of specific substances involved. The database is extracted from the national deaths database for England and Wales. Deaths are included if the underlying cause of death is regarded as resulting from drug-related poisoning, according to the current National Statistics definition. ${ }^{2}$ These are deaths coded according to the International Classification of Diseases Tenth Revision (ICD-10) for 2001 onwards. The codes used are listed in Box One.

The database covers accidents and suicides involving drug poisoning, as well as poisonings due to drug abuse and drug dependence, but not other adverse effects of drugs. The range of substances it contains is wide, including legal and illegal drugs, prescription drugs and over-the-counter medications. It does not include poisoning with non-medicinal substances such as household, agricultural or industrial chemicals. For each death,
the database includes every mention of a substance recorded on the death certificate or mentioned by the coroner. Almost all deaths on the database had a coroner's inquest. The underlying cause of death is recorded in addition to other information about the deceased, as described in Box Two.

## Results

## Number of deaths from drug-related poisoning by underlying cause

Table 1 gives the total number of deaths registered in each year from 2002 to 2006 , presented by their underlying cause. Each death is assigned an underlying cause of death which reflects the verdict of the coroner and the wording on the coroner's certificate. The number of deaths related to drug poisoning for males was 1,782 in 2006, a decrease of 6 per cent compared to 2005. The number of female deaths fell to 788 in 2006, a decrease of 10 per cent compared to 2005 . This is also the lowest recorded annual number since 1993 (the first year held within the database). Among males in the period 2002-06, similar proportions of deaths were due to 'mental and behavioural disorders due to drug use' ( 36 per cent) and intentional self-poisoning/poisoning of undetermined intent ( 35 per cent). Over half of drug-related poisoning deaths among females in this period were intentional self-poisonings and poisonings of undetermined intent (59 per cent).

## Number of deaths from drug-related poisoning where selected substances were mentioned on the death certificate

Table 2 gives numbers of deaths where specific substances were mentioned on the death certificate for 2002 to 2006. These figures need to

## Box one

| ICD-10 Underlying cause code | Description |
| :--- | :--- |
| F11-F16, F18-F19 | Mental and behavioural disorders due to drug use (excluding alcohol and tobacco) |
| X40-X44 | Accidental poisoning by drugs, medicaments and biological substances |
| X60-X64 | Intentional self-poisoning by drugs, medicaments and biological substances |
| Y10-Y14 | Poisoning by drugs, medicaments and biological substances, undetermined intent |
| X85 | Assault by drugs, medicaments and biological substances |

Number of deaths from drug-related poisoning by sex and underlying cause, 2002-06

|  | Females | 5 | 1 | 2 | 3 | 4 | 15 | 0.3 |

1 International Classification of Diseases, Tenth Revision - used to code causes of death from 2001 onwards.

## Box two

## For each death the database of drug-related poisonings includes:

## The underlying cause of death

Every mention of a substance recorded by the coroner in the cause of death section or elsewhere on the Coroner's certificate after inquest (Form 99(REV))

An indicator to show if alcohol is mentioned

Other information recorded at death registration such as age, sex, marital status, occupation and place of usual residence
be interpreted with some caution for the following reasons:

- in around 10 per cent of deaths on the database only a general description, such as 'drug overdose', is recorded on the coroner's certificate of death. These deaths do not contribute to the count of specific substances
- where more than one drug is mentioned on the death certificate, it is not always possible to tell which of them was primarily responsible for the death.
- some deaths may be counted in more than one category in these tables. For example, if heroin and cannabis are recorded on the death certificate, the death will be recorded once under heroin and once under cannabis. Therefore the numbers in each column cannot be added together to give a total number of deaths

As heroin (diamorphine) breaks down in the body into morphine, the latter may be detected at post mortem and recorded on the death certificate. Therefore a combined figure for deaths where heroin or morphine was mentioned on the death certificate is included in Table 2. The figure for cocaine in Table 2 includes deaths where cocaine was taken in the form of crack cocaine. It is not possible to separately identify crack cocaine from other forms of cocaine at post mortem.

Other evidence to distinguish the form of cocaine taken is rarely provided on death certificates.

In 2006, almost a third ( 31 per cent) of drug-related poisoning deaths mentioned more than one drug, or a 'multiple drug overdose' for example, and over a quarter ( 27 per cent) of deaths contained a mention of alcohol in addition to a drug.

There were 713 deaths involving heroin or morphine in 2006, a 15 per cent fall compared to 2005 . The number of deaths involving methadone however rose throughout 2002-06 to 241 in the latest year. There were 190 deaths involving cocaine, continuing the long-term upward trend. This was the highest number of deaths involving cocaine since 1993, when it was mentioned in only 11 deaths on the database.

There were 92 deaths involving amphetamines in 2006, with more than half of these being accounted for by deaths mentioning ecstasy. A small number of deaths mentioned Gamma-hydroxybutyrate (GHB) or cannabis ( 7 and 17 respectively). The number of deaths which mentioned benzodiazepines fell to 177 in 2006. This continues a long-term decreasing trend and was the lowest recorded number since 1993. Deaths involving barbiturates increased slightly between 2005 and 2006, to 17, but remained at low levels throughout 2002-06.

There were 336 deaths involving antidepressants in 2006, the lowest annual number since 1993. Compared to 2005 there was a decrease in all of the main antidepressant types, but with a particularly big decrease in deaths involving tricyclic antidepressants. The number of deaths mentioning dothiepin, for example, fell by 31 per cent compared to 2005 (and by 56 per cent compared to 2002). Deaths involving selective serotonin re-uptake inhibitors (SSRIs) such as fluoxetine, paroxetine and citalopram reached a peak in 2004 (105) but have since declined to 76 in 2006

Deaths involving paracetamol and its compounds declined in 2006 to 309 deaths, the lowest figure since 1993. Numbers of deaths fell by 40 per cent between 2002 and 2006. The overall figure for paracetamol includes those deaths where dextropropoxyphene was mentioned alone on the death certificate as, in England and Wales, this substance is very rarely ingested except in combination with paracetamol. The biggest impact on this decline was from deaths involving co-proxamol (paracetamol \& dextropropoxyphene compound formulation), where the number more than halved between 2005 and 2006, from 202 to 97 . There were 22 deaths involving aspirin in 2006, with similar low numbers throughout 2002-06.
The number of deaths involving codeine (not from compound formulation)

| Paracetamol \& dextropropoxyphene compound formulation (includes dextroprop without paracetamol) ${ }^{1}$ | 99 | 72 | 96 | 48 | 33 |
| Paracetamol \& codeine compound formulation | 7 | 8 | 9 | 14 | 7 |
| Paracetamol \& dihydrocodeine compound formulation | 5 | 6 | 3 | 5 | 1 |
| Paracetamol not from compound formulation | 22 | 33 | 28 | 26 | 29 |
| Codeine not from compound formulation | 14 | 11 | 21 | 14 | 22 |
| Dihydrocodeine not from compound formulation | 27 | 26 | 18 | 31 | 33 |
| Aspirin | 5 | 1 | 3 | 3 | 2 |
| Tramadol | 7 | 8 | 9 | 6 | 20 |

1 Dextropropoxyphene is very rarely ingested except in combination with paracetamol in England \& Wales.
and tramadol increased to 60 and 81 respectively, which for both were the highest numbers since 1993.

## Deaths related to drug misuse

In 2000 the Advisory Council on the Misuse of Drugs published a report, Reducing Drug Related Deaths. ${ }^{3}$ In response to this report's recommendations on improving the present system for collecting data on drug-related deaths, a technical working group was set up. This group, consisting of experts across government, the devolved administrations, coroners, toxicologists and drugs agencies, proposed a headline indicator for drug-misuse-related deaths as part of the Government's Action Plan ${ }^{4}$ to reduce the number of these deaths. This indicator also takes into account the information needs of the European Monitoring Centre for Drugs and Drug Addiction. The definition of the indicator is 'deaths where the underlying cause is poisoning, drug abuse or drug dependence and where any of the substances controlled under the Misuse of Drugs Act (1971) are involved'. This definition has been adopted across the United Kingdom. The baseline year for monitoring deaths related to drug misuse was set as 1999.

The definition of the headline indicator using ICD-10 is shown in Box Three. The definition using ICD-9 was published in a previous annual report. ${ }^{1}$

| Table 3 Number of d <br> and country, | Number of deaths related to drug misuse ${ }^{1}$ by sex and country, ${ }^{2}$ 2002-06 |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| England and Wales |  |  |  |  |  |
|  | 2002 | 2003 | 2004 | 2005 | 2006 |

| Drug misuse deaths as a percentage of all deaths on the database | 57 | 55 | 54 | 58 | 61 |

1 As defined by the current headline indicator on drug misuse (see Box Three).
2 Figures for England and Wales include deaths to non-residents. The separate figures for England and for Wales include only deaths to residents of those countries.

## Box three

Cause of death categories included in the headline indicator of drug misuse deaths (the relevant codes from ICD-10 are given in brackets):
a) deaths where the underlying cause of death has been coded to the following categories of mental and behavioural disorders due to psychoactive substance use (excluding alcohol, tobacco and volatile solvents):
(i) opioids (F11)
(ii) cannabinoids (F12)
(iii) sedatives or hypnotics (F13)
(iv) cocaine (F14)
(v) other stimulants, including caffeine (F15)
(vi) hallucinogens (F16) and
(vii) multiple drug use and use of other psychoactive substances (F19)
b) deaths coded to the following categories and where a drug controlled under the Misuse of Drugs Act 1971 was mentioned on the death record:
(i) Accidental poisoning by drugs, medicaments and biological substances (X40-X44)
(ii) Intentional self-poisoning by drugs, medicaments and biological substances (X60-X64)
(iii) Poisoning by drugs, medicaments and biological substances, undetermined intent (Y10-Y14)
(iv) Assault by drugs, medicaments and biological substances (X85) and
(v) Mental and behavioural disorders due to use of volatile solvents (F18)

## Notes

1. Deaths coded to opiate abuse which resulted from the injection of contaminated heroin have been included in the indicator. This differs from the approach taken in Scotland, where these deaths have been excluded. This is because the General Register Office for Scotland (GROS) is able to identify deaths which occurred as a result of the use of contaminated heroin, whereas in England and Wales, these deaths cannot be readily identified. In practice, in England and Wales, they will only be included where the drug was mentioned on the death record and the death was coded to one of the ICD codes on the ONS database of drug-related poisonings and not to an infection code.
2. Specific rules were adopted for dealing with compound analgesics which contain relatively small quantities of drugs listed under the Misuse of Drugs Act, the major ones being dextropropoxyphene, dihydrocodeine and codeine. Where these drugs are mentioned on a death record, they have been excluded if they are part of a compound analgesic (such as co-proxamol, co-dydramol or co-codamol) or cold remedy. Dextropropoxyphene has been excluded on all occasions, whether or not paracetamol or a compound analgesic was mentioned. This is because dextropropoxyphene is rarely, if ever, available other than as part of a paracetamol compound. However, codeine or dihydrocodeine mentioned alone were included in the indicator. This is because they are routinely available and known to be abused in this form. This approach is the same as that taken by GROS.
3. Drugs controlled under the Misuse of Drugs Act 1971 include class A, B and C drugs.
4. Information on the cause of death categories used to define the indicator in ICD-10 can be found in the report in Health Statistics Quarterly $33 .{ }^{1}$

Table 3 shows numbers of deaths related to drug misuse, using this definition and the current list of drugs controlled under the Misuse of Drugs Act, for 2002 to 2006. Because the indicator is based on the current list of drugs controlled under the Misuse of Drugs Act, earlier years' data have been updated to reflect additional substances.

The total number of drug misuse deaths in 2006 was 1,573 . This was lower than the 2002 total $(1,613)$ but drug misuse deaths now form a larger percentage of the total deaths on the database. In 2006 they made up 61 per cent of the total, the highest proportion since 1993. In 2006, 70 per cent of male deaths on the database were related to drug misuse, a much higher proportion than for females ( 41 per cent).

Table 4a shows deaths involving drug misuse by underlying cause of death. In 2006, 'mental and behavioural disorders due to drug use' formed the largest proportion of deaths related to misuse in males (51 per cent). The distribution in females was more evenly divided between mental and behavioural disorders ( 31 per cent), accidental poisoning (35 per cent) and self-poisoning ( 33 per cent). Among males, the highest numbers of deaths occurred in the 30-39 and 20-29 age groups (Table $4 b$ ), whereas females deaths were more evenly distributed across these and older age groups.

Figure 1 shows the trend in mortality rates by age group for deaths related to drug misuse. From 1993 to 2002, the age group with the highest rate was men aged 20-29. The recent decline in rates in this age group, and an increase among men aged 30-39, means that the latter age
group has had the highest rate since 2003. Rates among men aged 40-49 increased by nearly half between 2002 and 2006 ( 48 per cent). In 2006, rates for females were lower than for males in every age group and, as with men, the highest rate was among those aged 30-39.

## Figure 2 Mortality rates ${ }^{1}$ for all drug related poisoning, and drug misuse, by sex, 2002-06

## England and Wales

## Age-standardised death rates for all drug-related poisoning, and drug misuse

Figure 2 shows trends in mortality rates for both drug-related poisoning and deaths related to drug misuse from 2002 to 2006. Rates for males increased throughout the 1990s for both all drug-related poisonings and those involving drug misuse, but started to decline from 2001 onwards. Figure 2 shows that rates have been relatively stable since 2003 but with a small decrease in the rate for all drug-related poisoning in 2006 compared to 2005. Female rates for both drug misuse and all drug-related poisoning have remained stable since 1993, although Figure 2 shows there was a small decline in the latter in 2006 compared to the previous four years.

## Age-standardised death rates for selected substances

Figure 3 shows the trend in mortality rates from drug-related poisoning for selected substances from 2002 to 2006. The death rate for heroin/ morphine for males was higher than for other substances throughout this period. The rate for paracetamol and its compounds decreased in males by almost half ( 47 per cent) between 2002 and 2006. There was a similar decrease in the rate for female deaths involving paracetamol (40 per cent between 2002 and 2006). This means that although the rate for paracetamol was highest for females until 2004, in 2005 and 2006 the highest rate has been for deaths involving antidepressants. Paracetamol
and antidepressants are the substances most commonly used in suicides (which make up the majority of drug-related poisoning deaths among females).

# Report: <br> Life expectancy at birth and at age 65 by local areas in the United Kingdom, 2004-06 

## Introduction

This report presents the latest figures on male and female period life expectancy at birth for local areas in the UK, constituent countries and English regions for 2004-06. For the first time male and female period life expectancy at age 65 for 2004-06 is also included. The term local area refers to Local and Unitary Authorities in England and Wales, Council areas in Scotland and Local Government District areas in Northern Ireland. These figures were calculated by the Office for National Statistics, except those for Scotland which were calculated by the General Register Office for Scotland (GROS) using the same methods.

Life expectancy results for local areas in Scotland for 2004-06 were first published in a report on 4 September 2007 on the GROS website at: www.gro-scotland.gov.uk/statistics/publications-and-data/lifeexpectancy/index.html

All figures are three-year averages, produced by aggregating deaths and population estimates across each three-year period, to provide large enough numbers to ensure that the figures presented are sufficiently robust. Two local authorities, City of London and Isles of Scilly, are excluded from the results because of the small populations and small numbers of deaths.

## Previous life expectancy reports

All life expectancy results for English regions and local authorities in England and Wales from 2000-02 to 2003-05 have been revised. Life expectancies for local areas in Scotland have been revised by GROS for the periods 2002-04 and 2003-05. These revised local area life expectancies can be found on the National Statistics website at: www. statistics.gov.uk/statbase/Product.asp?vlnk=8841

Results for Scotland can also be found in reports released on the GROS website at: www.gro-scotland.gov.uk/statistics/publications-and-data/ life-expectancy/index.html

The mortality data used to calculate the revised local area life expectancy figures are the same as those used in previously published figures. However, ONS published revised mid-year population estimates for

England and Wales at local authority level on 22 August 2007 for all years between 2002 and 2005. This is due to improvements made to the methodology used to produce the mid-year population estimates, principally the distribution of the national population to local areas. More information about population statistics and the recent improvements to methodology can be found on the National Statistics website at: www. statistics.gov.uk/statbase/Product.asp?vlnk=601

The revisions to Scottish local area life expectancy figures followed on from revisions to Scottish mid-year population estimates after a review of methodology identified an error in the figures originally published for six local areas.

## Interpretation of period life expectancy at birth and at age 65

Life expectancy at a given age for an area in a given time period is an estimate of the average number of years a person of that age would survive if he or she experienced the particular area's age-specific mortality rates for that time period throughout the rest of his or her life. The figure reflects mortality among those living in the area in each time period, rather than mortality among those born in each area. It is not therefore the number of years a person in the area in each time period could actually expect to live, both because the death rates of the area are likely to change in the future and because many of those in the area will live elsewhere for at least some part of their lives.

Life expectancy at birth is also not a guide to the remaining expectation of life at any given age. For example, if female life expectancy was 80 years for a particular area, life expectancy of women aged 65 years in that area would exceed 15 years. This reflects the fact that survival from a particular age depends only on the mortality rates beyond that age, whereas survival from birth is based on mortality rates at every age. Neither is life expectancy at age 65 the actual time a resident of a given area, aged 65 this year, can expect to live.

## Summary of results

## Life expectancy at birth

Results for 2004-06 show a familiar geographic pattern, with inequalities in life expectancy continuing to persist across the UK. The South West, South East and East of England continued to have the highest life expectancies at birth, while figures were lowest in Scotland and the North East and North West of England. For males there was a difference of 3.9 years between Scotland as a whole which had the lowest life expectancy ( 74.6 years) and the South East and South West of England, where life expectancy was highest ( 78.5 years). For females the gap between Scotland and the South West of England (79.6 and 82.7 years respectively) was 3.1 years.

In 2004-06 for the first time all local areas in the UK had a male life expectancy at birth of more than 70 years. As in 2003-05, the local area with lowest male life expectancy was Glasgow City ( 70.5 years). The local area with the highest life expectancy for males was Kensington and Chelsea ( 83.1 years), 12.6 years more than Glasgow City. Kensington and Chelsea also had the highest life expectancy for females ( 87.2 years), 10.2 years more than Glasgow City, the area with the lowest figure ( 77.0 years).

The local areas with the highest and lowest male and female life expectancy at birth in the UK in 2004-06 are presented in Boxes One and Two respectively.

## Life expectancy at age 65

Life expectancies at age 65 for the constituent countries of the UK and English regions in 2004-06 show a similar geographical pattern to the results at birth. The lowest estimates were in Scotland and the North East and North West of England; the highest were in the South East and

| 424 | Renfrewshire | Scotland | 78.4 |
| 423 | Manchester | North West | 78.6 |

South West of England. The gap between the areas with the highest and lowest life expectancies at 65 for women was similar to the gap for men. Women in Scotland had a life expectancy at 65 of 18.6 years, 2.2 years lower than women in the South West of England (20.8 years). Men in Scotland had a life expectancy at 65 of 15.9 years, 2.1 years lower than the result for men in the South East and South West who could expect to live another 17.9 years.

At local area level in 2004-06, Glasgow City had the lowest male life expectancy at age 65 ( 13.8 years). This was the only area in the UK where the life expectancy at age 65 was less than 14 years. The local area with the highest male life expectancy at 65 was Kensington and Chelsea (22.0 years), 8.2 years more than Glasgow City. Kensington and Chelsea also had the highest life expectancy at 65 for women ( 24.8 years), 7.5 years more than Glasgow City, the area with the lowest figure ( 17.3 years).

The local areas with the highest and lowest life expectancy at age 65 for men and women in the UK in 2004-06 are presented in Boxes Three and Four respectively.

Table 1 includes results for all local areas in the UK for both life expectancy at birth and life expectancy at 65 for 2004-06, and their relative rank order. Results are presented alphabetically by local area name within each constituent country and English region.

## Results on the National Statistics website

The results presented in this report can also be found presented with 95 per cent confidence intervals in a series of Excel workbooks on the National Statistics website at: www.statistics.gov.uk/statbase/Product. asp?vlnk=8841

The four workbooks contain

- Results for the United Kingdom - figures for 1991-93 to 2004-06 for the UK, England and Wales, England, Wales, Scotland and Northern Ireland. Tables are also included showing the rank order of local authorities in the UK in 2004-06
- Results for England and Wales - figures for 1991-93 to 2004-06 for local authorities in England and Wales, and Government Office Regions in England
- Results for Scotland - figures for 1991-93 to 2004-06 for Council areas and Health Boards in Scotland
- Results for Northern Ireland - figures for 1991-93 to 2004-06 for Local Government District areas and Health and Social Service Boards in Northern Ireland

Results for 1991-93 to 2004-06 are published on the National Statistics website as a set of animated maps to show the change in life expectancy at local area level over time, these are available at: www.statistics.gov. $\mathrm{uk} / \mathrm{CCI} /$ nugget.asp?ID=1850\&Pos=1\&ColRank=1\&Rank=374

## Comparison with national results

Until 2005 the Government Actuary's Department (GAD) published national interim life tables for the UK and constituent countries. In January 2006 responsibility for this work passed to ONS. This year ONS has calculated revised interim life tables for 1990-92 to 2003-05 and new 2004-06 tables. The mortality data for England and Wales used in the revised national interim life tables are now based on all deaths registered in a year, rather than all deaths that occurred in a year as they were previously. The national interim life tables are the definitive life expectancy figures for the entire UK and constituent countries and are published on the National Statistics website at: www.statistics.gov.uk/ statbase/Product.asp?vlnk=14459

To provide comparisons for local area and regional figures, ONS has also calculated national life expectancy results, which are included in Table 1 These were produced using the same methods as the subnational results, with abridged life tables in which deaths and populations are aggregated into age groups. The national interim life tables are calculated using complete life tables (based on single years of age), so the two sets of national figures may differ very slightly (normally by less than 0.1 years for England and Wales).

Figures for England will also differ slightly from the national interim life table results because of a difference in the handling of deaths of nonresidents. For this report, the deaths of non-residents have been included in the mortality figures for England and Wales but are excluded from the data for England and Wales separately. However, for the national interim tables, the deaths of non-residents in England and Wales have been included in the mortality data for England (but not Wales).

## Methods of calculation

Abridged life tables were constructed using standard methods. ${ }^{1,2}$ Separate tables were constructed for males and females. The tables were created using annual mid-year population estimates and deaths registered in each year. A detailed description of the standard methods and notation associated with the calculation of life expectancy can be found on the Government Actuary's Department website at:

Methods: www.gad.gov.uk/Demography_data/Life_Tables/methodology.asp Notation: www.gad.gov.uk/Demography_data/Life_Tables/notation.asp

The calculation of confidence intervals (available on the National Statistics website) used the method developed by Chiang. ${ }^{3}$ A report which details research undertaken by ONS to compare methodologies to allow the calculation of confidence intervals for life expectancy has been published as No. 33 in the National Statistics Methodology Series. The report, 'Life expectancy at birth: methodological options for small populations' also presents research carried out to establish if there is a minimum population size below which the calculation of life expectancy may not be considered feasible. It can be found on the National Statistics website at: www.statistics.gov.uk/methods_quality/publications.asp

Using the recommendations included in this report ONS has previously published experimental life expectancy at birth figures for wards in England and Wales based on deaths from 1999-2003. These are available at: www.statistics.gov.uk/statbase/Product.asp?vlnk=14466

An example of a life table constructed using the same method used to calculate life expectancy and confidence intervals in this report can be found at: www.statistics.gov.uk/statbase/Product.asp?vlnk=8841

## Report:

# Infant and perinatal mortality by social and biological factors, 2006 

This report presents statistics on stillbirths and infant deaths registered in England and Wales that occurred in 2006. Only infant deaths that have been linked to their corresponding birth records are included as linkage enables analysis of infant and perinatal deaths by risk factors collected at birth registration. These include birthweight, mother's age at birth of child, mother's country of birth, marital status, parity and father's socioeconomic status based on his occupation.

In 2006, 3,292 infant deaths occurred in England and Wales of which 3,223 ( 98 per cent) were linked to their birth records. Of the 69 records that were not linked, 38 were born outside England and Wales (and therefore not registered in England and Wales) and 31 were not linked because no record of the birth could be found. The linkage rate for 2006 is comparable with that for previous years since linkage began in 1975.

In 2006, of all the linked infant deaths 1,729 (54 per cent) were early neonates (babies dying under 7 days), 2,289 ( 71 per cent) were neonatal deaths (babies dying under 28 days) and 934 ( 29 per cent) were postneonatal deaths (babies dying aged 28 days and over but under one year).

## Key findings

- The infant mortality rates for very low birthweight babies (under 1,500 grams) and low birthweight babies (under 2,500 grams) were 195.6 and 41.3 deaths per 1,000 live births respectively compared with a rate of 1.7 among normal birthweight babies $(2,500$ grams and over). Fifty per cent of infant deaths occurred among very low birthweight babies
- There were 924 stillbirths weighing less than 1,500 grams delivered at 24-27 weeks gestation. This represented 96 per cent of all stillbirths delivered at 24-27 weeks and 56 per cent of all very low birthweight stillbirths
- The infant mortality rate was highest among babies of mothers aged under 20 ( 6.4 deaths per 1,000 live births) followed by babies
of mothers aged 40 and over ( 5.9 per 1,000 live births). The infant mortality rate was lowest among babies with mothers in the 30-34 age group ( 4.1 per 1,000 live births)
- Babies of mothers aged 40 and over had the highest stillbirth and perinatal mortality rates at 8.6 and 12.0 per 1,000 births respectively
- Babies of mothers born in Pakistan and the Caribbean had particularly high infant mortality rates ( 9.4 and 8.8 deaths per 1,000 live births respectively) compared with the overall infant mortality rate of 4.8 per 1,000 live births. The perinatal mortality rate was also particularly high in these two groups
- The registration type with the highest infant mortality rate was the sole registered births ( 6.3 deaths per 1,000 live births). This was followed by babies born outside marriage jointly registered by both parents giving different addresses ( 6.2 deaths per 1,000 live births)
- Babies born inside marriage to women with three or more previous children had high infant mortality at 6.9 deaths per 1,000 live births
- For births inside marriage combined with births outside marriage jointly registered by both parents, babies of fathers in 'routine occupations' had an infant mortality rate of 6.2 deaths per 1,000 live births compared with babies of fathers in the 'large employers and higher managerial occupations' who had an infant mortality rate of 2.6 per 1,000 live births
- Seventy-four per cent of all infant deaths were related to events occurring in pregnancy (that is, congenital anomalies, antepartum infections and immaturity related conditions) as were 87 per cent of all neonatal deaths. For postneonatal deaths, 31 per cent were related to congenital anomalies, 14 per cent were from infections, 13 per cent were sudden infant deaths and 10 per cent were from immaturity related conditions

## Explanatory notes

## Database changes

The figures presented in this report relate to live births, stillbirths and infant deaths that occurred in 2006 and were on our database at 17 September 2007. These figures are provisional.

Birthweight information was not available for 0.9 per cent of live births. Efforts are currently underway to obtain this information from the Registrars and Trusts.

## National Statistics Socio-Economic Classification (NS-SEC)

In 2001, the National Statistics Socio-Economic Classification (NS-SEC) replaced the Registrar General's Social Class Classification. Although the eight-class version of NS-SEC is used here, the categories can be aggregated to produce five- and three-class versions of NS-SEC.

## Mother's country of birth

These groupings differ slightly from those used up to 1997. In addition, the countries included in 'Other European Union' changed in 2004 to reflect the EU enlargement that took place on 1 May 2004.

## United Kingdom

England, Wales, Scotland, Northern Ireland

## Elsewhere in United Kingdom

Channel Islands, Isle of Man, UK (part not stated)

## Outside United Kingdom

## Irish Republic

Irish Republic, Ireland (part not stated)

## Other European Union

Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Faroe Islands, Finland, France, Germany, Greece, Greenland, Hungary, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden

## Rest of Europe

All other European countries including Turkey, Russia and former Soviet republics

## Commonwealth

Australia, Canada and New Zealand

New Commonwealth
Asia
Bangladesh, India, Pakistan

## East Africa

Kenya, Malawi, Tanzania, Uganda, Zambia
Southern Africa
Botswana, Lesotho, Namibia, South Africa, Swaziland

## Rest of Africa

Cameroon, The Gambia, Ghana, Mauritius, Mozambique, Nigeria, Seychelles, Sierra Leone, Zimbabwe

## Far East

Brunei, Malaysia, Singapore

## Caribbean

Anguilla, Antigua, Bahamas, Barbados, Belize, Bermuda, British Virgin Islands, Cayman Islands, Dominica, Grenada, Guyana, Jamaica, Montserrat, St Christopher and Nevis, St Lucia, St Vincent, Trinidad and Tobago, Turks and Caicos Islands Rest of the New Commonwealth
Cook Islands, Falkland Islands, Fiji, Gibraltar, Kiribati, Maldives, Nauru, New Hebrides, Papua New Guinea, St Helena, Solomon Islands, Sri Lanka, Tonga, Tuvalu, Vanuatu, Western
Samoa, British Indian Ocean Territory
Rest of the World and not stated

## Report:

## Infant and perinatal mortality 2006: health areas, England and Wales

## Introduction

This report gives provisional statistics on infant deaths registered in 2006, and live births and stillbirths occurring in 2006, in England and Wales, for each Government Office Region and Strategic Health Authority in England and Local Health Board in Wales.

## Perinatal and infant mortality

There were 3,602 stillbirths and 1,761 deaths at ages under seven days registered in England and Wales in 2006. The stillbirth rate remained at 5.4 per thousand live births, from 2005 to 2006 . The perinatal rate also remained unchanged at 8.0 per thousand live births and stillbirths. (Table 1).

1 See the background note 'Legal definition of stillbirths'.
2 Numbers of deaths shown are based on annual occurrences for years 1993 to 2005, and on annual registrations for all other years.
3 Per 1,000 live births and stillbirths.
4 Per 1,000 live births.
5 Stillbirth figures and rates for 2003 and 2004 are different from those released previously in DH3 - volumes 36 and 37 , and in HSQ - editions 23 and 27 . This is due to the late notification of an extra 27 stillbirths for 2003 and 154 stillbirths for 2004. This also affects perinatal rates for 2003 and 2004.
6 The live births figure differs from that released previously on 7 June 2007.

The neonatal mortality rate (deaths under 28 days) increased slightly to 3.5 per thousand live births in 2006, from 3.4 in 2005. The postneonatal mortality rate (deaths between 28 days and one year) fell to 1.5 per thousand live births, from 1.6 per thousand live births in 2005.

There were 3,368 infant deaths (at ages under one year) registered in England and Wales in 2006, giving an infant mortality rate of 5.0 deaths per thousand live births. This is the same rate as in 2005 and hence remains the lowest rate ever recorded in England and Wales.

The infant mortality rate over the period 1976 to 2006 by age at death in the neonatal and postneonatal period is shown in Figure 1. The infant mortality rate fell by 65 per cent over this period, while the neonatal and postneonatal rates all fell by 64 and 67 per cent respectively. However, these declines were not constant over the period, being mainly concentrated in the earlier years.

## Geographical variation in infant mortality

There was considerable variation in the infant mortality rate across the health authorities. In 2006, West Midlands had the highest infant mortality rate among the Strategic Health Authorities in England at 6.4 deaths per thousand live births. South West had the lowest at 4.0 deaths per thousand live births (Table 2). Table 3 shows that the highest infant mortality rate among the Local Health Boards in Wales was 7.2 deaths per thousand live births in Anglesey.

## Live Births and birthweight

There were 669,601 live births in England and Wales in 2006, compared with 645,835 in 2005 . This is a rise of 3.7 per cent and the fifth successive increase in the annual number of live births.

Table 2 shows the number of births and the proportions of low and very low birthweight babies for England and Wales and Strategic Health Authorities in England in 2006. Of those live births with a stated
birthweight in England and Wales, 7.6 per cent had a low birthweight (under 2,500 grams) and 1.2 per cent had a very low birthweight (under 1,500 grams). The corresponding percentages in 2005 were 7.6 and 1.3 respectively.

Low birthweight is one of the known risk factors for infant deaths ${ }^{1}$. Among the Strategic Health Authorities in England, West Midlands had the highest proportions of very low birthweight babies, 1.5 per cent, as well as having the highest infant mortality rate (see above). West Midlands also had the highest proportion of low birthweight babies with 8.4 per cent of babies weighing under 2500 g. The Strategic Health Authority with the lowest proportion of low birthweight babies was South West with 6.5, whilst the lowest proportion of very low birthweight babies was in South East Coast with 1.0 per cent.

Among the Local Health Boards of Wales in 2006, the percentage of low birthweight babies was highest in Blaenau Gwent ( 8.7 per cent) and lowest in Ceredigion ( 4.8 per cent) (Table 3). The proportion of very low birthweight babies ranged from 0.5 per cent in Ceredigion to 1.9 per cent in Newport.

## Revisions to live births

This report introduces the revised live births figures for 2006 in England and Wales. The revision was necessary due to the late receipt at ONS of seventy records relating to live births occurring in 2006. Therefore, the numbers of live births given here do not correspond with those published in the report on live births in Population Trends $128 .{ }^{2}$

## Background Notes

## Statistics in the Report

Although the live birth numbers are based on births occurring in 2006, the mortality data here are based on deaths registered in 2006. However, in line with ONS practice in publishing mortality data, final national mortality statistics (including rates) will be based on deaths occurring in the year. It is intended that these statistics will be available in late 2007.

Additionally, in Table 1 numbers of deaths for 1993 to 2005 are based on occurrences in these years, while numbers for years prior to 1993 are based on registrations in each year.

Stillbirth and perinatal mortality figures for 2003 and 2004 have been revised. This is because some register offices in England and Wales failed to notify ONS, in line with regulations, of some stillbirths that occurred in 2003 and 2004. These have now been received by ONS.

Mortality rates in Tables 2 and 3 that are calculated from fewer than 20 deaths are distinguished by italic type as a warning to the user that their reliability may be affected by the small number of events.

Areal statistics in this Report are derived from the usual residence at the time of birth or death. If the usual residence was outside England and Wales, these events are included in the aggregate for 'England and Wales', but excluded from the figures for individual health areas and Government Office Regions.

## Recording of birthweight

Since 1975 ONS (formerly OPCS) has obtained the birthweight of a baby from information provided to the registrar of births and deaths by the local health services. In 2006, birthweight was recorded for 99.1 per cent of all live births.

* Note: To protect confidentiality all counts lower than 5, and all rates based on fewer than 5 events, have been suppressed.

1 Stillbirths and deaths at ages under 1 week.
2 Deaths at ages under 4 weeks.
3 Deaths at ages under 1 year.
4 Per 1,000 live and stillbirths.
5 Per 1,000 livebirths.

## Legal definition of stillbirths

On 1 October 1992 the legal definition of a stillbirth was changed from a baby born dead after 28 or more weeks completed gestation to one born dead after 24 or more weeks completed gestation. This means that perinatal and stillbirth data for 2006 can be compared with data only from 1993 onwards.

## General

More details on the above, and on other aspects of stillbirth and infant mortality data, can be found in the ONS annual reference volume Mortality statistics: childhood, infant and perinatal 2005, series DH3 no 38, published in March 2007.3

# Annual Update: 

 general

## Introduction

This update summarises some of the findings from the annual reference volume Mortality statistics: general 2005 (series DH1 no. 38), ${ }^{1}$ which was published in October 2007. It presents data and analysis on various measures of mortality and details recorded at death registration in England and Wales, including:

- mortality rates by single year of age
- years of life lost
- monthly variation in mortality
- place of occurrence of death
- country of birth of the deceased
- type of death certification
- geographical variation in mortality

The annual reference volume contains more detailed information on these, and other, themes. It contains long-term time series for crude death rates, standardised mortality ratios (SMRs) and age-specific mortality rates, some going back to 1841 . Infant mortality rates are also given from the 19th century onwards, as well as stillbirth and perinatal mortality rates from 1931. The volume also presents mortality data by country of residence within the UK, and by region of residence. More detailed information for local and health authorities can be found in Key Population and Vital Statistics. ${ }^{2}$

## Mortality rates in 2005

In 2005, there were 243,324 male deaths and 269,368 female deaths in England and Wales. Figure 1 contains age-specific mortality rates for single years of age for both males and females in 2005. This shows a typical age-specific pattern of mortality. Beyond the age of 1, mortality rates fall rapidly and are at their lowest among children under 12 years. During the teenage period, rates rise more rapidly for males than females Male rates show the most rapid increase between the ages of 15 and 18, after which there is a levelling off in the male rate during the early adult years. Beyond the age of 30 , the rate of increase in mortality for males and females is similar, although male rates continue to be higher than female rates at every age group.

## Years of life lost

Analyses of the effects of premature death can be expressed by the number of years of life lost. In calculating this, it is assumed that

Figure $1 \quad$ Age-specific mortality rates by sex, 2005

England and Wales

Source: DH1 no. 38, Table 8
everyone may live to some arbitrarily chosen age $(65,75$ or 85 in the DH 1 volume) and that death at a younger age means that some future years of life have been lost. Using age 65 for both males and females, it is also possible to estimate years of working life lost due to premature death. Comparisons can be made between selected causes with the aim of illustrating their relative effects.

A total of 758,000 years of working life (ages 15 to 64 ) were lost for males in 2005 compared with 470,000 for females. Of the selected causes in Table 25 of the annual reference volume, the cancers that are presented in total account for a large proportion of these: 111,000 years for men and 136,000 for women. However, when cancers are considered on a site-specific basis, the causes of death that contributed most to the total for men were ischaemic heart disease ( 83,000 years lost), suicide including open verdicts (65,000 years) and land transport accidents ( 54,000 years). For women, breast cancer caused the highest number of years of working life lost $(45,000)$, followed by diseases of the liver ( 22,000 years), lung cancer ( 20,000 years) and suicide including open verdicts ( 19,000 years). Land transport accidents caused the loss of 14,000 years of working life for women; this is just over a quarter of the number lost for men due to such accidents.

England and Wales

Source: DH1 no. 38, Table 19

## Monthly variation

Annualised monthly ratios show seasonal variation in mortality over the year. They allow for the variation in the number of days between months, and include all deaths where the date of occurrence was known. Figure 2 shows how these ratios change through the year for males and females. The patterns for males and females are very similar although the female ratios were higher than males in the winter months but lower for the remaining months. The ratios for each sex in 2005 were highest in January, while the lowest were in September. From the peak in January, the ratios decreased through the spring and summer months, and then increased again from September through to December. This pattern shows that higher mortality is experienced in the winter than in other months. ${ }^{3}$ The seasonal pattern is found for most causes of death, particularly respiratory and circulatory diseases. Deaths from cancer, however, show little variation over the year.

## Place of occurrence

More than half of all deaths in England and Wales occur in NHS hospitals or in other NHS communal establishments for the care of the sick: 60 per cent of male and 57 per cent of female deaths occurred in such places in 2005 (Table 1). Over a fifth ( 22 per cent) of male deaths occurred in the deceased's own home, while 15 per cent of female deaths occurred here. Conversely, a greater proportion of female deaths than male deaths occurred in other communal establishments such as residential homes for the elderly ( 9.2 per cent of female deaths compared with 3.6 per cent of male deaths). This most likely reflects women's longer life expectancy: at the same ages, more women will have been widowed than men and so are more likely to be living in residential or nursing care homes for the elderly at the time of death.

Around 5 per cent of all deaths occurred in hospices. However, this figure is an underestimate because hospice or palliative care wards that are situated within NHS hospitals may not be identified separately by the person registering the death. This means that ONS is unable to include these deaths with those in freestanding hospices.

## Country of birth of deceased

Of those who died in 2005, 8.0 per cent had been born outside the UK, compared with 4.8 per cent in 1981 and 5.9 per cent in 1991. Just over a fifth ( 21 per cent) of those born outside the UK were born in another European Union country, excluding the Irish Republic.

## Type of death certification

More than three-quarters ( 78 per cent) of deaths in 2005 were certified by a doctor. Twenty-three per cent of the deaths certified by a coroner (4.9

Source: DH1 no. 38, Table 22
per cent of all deaths) were subject to an inquest, while the remaining 77 per cent were subject to a post-mortem only (Table 2).

The proportion of deaths certified by a coroner varied considerably by cause of death. Most injury and poisoning deaths ( 83 per cent) were certified by a coroner and nearly all of these ( 96 per cent) were subject to an inquest (with or without post mortem). Deaths due to ischaemic heart disease had a relatively high proportion certified by a coroner (48 per cent), which reflects the fact that deaths from this cause can be sudden and unexpected. Deaths from long-term illnesses such as cancer, however, have a far lower proportion ( 5.8 per cent in 2005) certified by a coroner.

## Geographical variation

The annual reference volume presents standardised mortality ratios (SMRs) for the constituent countries of the United Kingdom. The SMRs are based on the standard of $\mathrm{UK}=100$ for each cause and sex. Scotland had the highest all causes SMR for both males and females in 2005, while England had the lowest. Looking at selected cause groups, Scotland had the highest SMRs for the majority of groups. However Northern Ireland had the highest SMRs for diseases of the nervous, respiratory and genito-urinary systems while England had highest SMRs for diseases of the musculoskeletal system. In 2005, among the government office regions, the North East had the highest SMRs for both males and females while the South West had the lowest. Further geographical analyses of mortality can be found in Key Population and Vital Statistics ${ }^{2}$ and Health Statistics Quarterly. ${ }^{4}$

## Background note

The mortality rates used in this update were calculated using population estimates for mid-2005 which were published on 24 August 2006. These estimates incorporate the findings of the Local Authority Population Studies, the results of which were published in July 2004. Further information on population estimates, and their methodology, can be found on the National Statistics website at: www.statistics.gov.uk/popest
